THE METAL WORKER.

NEW YORK AND CHICAGO.

Saturday, July 1, 1893.

DAVID WILLIAMS, - PUBLISHER

BUSINESS OFFICES:

NEW YORK.....96-102 Reade Street.
PHILADELPHIA.....220 South Fourth Street.
BOSTON.....146 Franklin Street.
PITTSBURGH..... Room 509 Hamilton Building.
CHICAGO.....59 Dearborn Street, cor. Randolph.
CINCINNATI.....Rooms 22-24 Pickering Building.
ST. LOUIS.....Bank of Commerce Building.
CLEVELAND.....312 The Cuyahoga.

BRITISH AGENCY: The Ironmonger, 42 Cannon street, London, England.

Practical Charity.

The truth of the old proverb, "Heaven helps those who help themselves," is inc ontestable, and the best method for putting helpless men into the way of becoming self-reliant, useful citizens is to teach them to help themselves. Such a wise effort is that of the Baron de Hirsch Trade Schools of New York, for training destitute Russian Jews in useful handicrafts, of which institution we give some account in another column of this paper. This establishment is a branch of a great enterprise instituted by the distinguished Hebrew philanthropist above named, by which he seeks to improve the condition of his fellow-religionists who have been driven from their homes in Europe, and who too often land in America destitute and friendless, without knowledge of the language or any means of livelihood; and this through no fault of their own. Just at this point the younger men and boys find a means provided for them by which they can learn a useful trade, which will give them an assurance of independence in the future. They are generously assisted during their time of pupilage, if necessary, by free provision of food, clothes and shelfer, and at the end of their term of instruction are helped to obtain employment, and launched upon their new life well equipped to become useful citizens of their adopted country. It is not proposed that the men so trained shall be turned out to swell the already overcrowded ranks of labor in our Eastern cities, but they are encouraged to go further afield and fill gaps in the newer portions of the Republic, where their services are really needed. The large-hearted, practical benevolence of the wealthy members of the Hebrew race toward their poorer brethren has often been signally instanced both in Europe and the United States, and in no case more brightly than in the institution we allude to. It differs, of course, from most of the trades schools of this country, in that it is a purely charitable institution, but it is charity on a common-sense basis which deserves consideration, for there is a wide field for similar work outside the Hebrew race.

The Workman and the Fair.

One of the greatest misfortunes to the country at large that will result from the incorrect impression of exorbitant cost of seeing the World's Fair is the effect of this impression on the working man. It will prevent many from making the effort to see it and deprive them of a great pleasure. The pleasure lost is a comparatively small matter, but the amount of invaluable information that might be obtained by the sightseer, whether he be workman or tradesman, in examining exhibits and watching processes of manufacture, is incalculable. In grasping the magnitude of the exposition as a whole or in detail there is an incentive to progress and an inspiration to attempt greater things that is priceless. The value of an object lesson is generally understood and the fair is an object lesson of infinite diversity. Of the millions who will gaze on its wonders each will gather some valuable impression to be used advantageously at a later period, and the amount of knowledge thus disseminated could be imparted in no other way. A notable feature of this fair to those who have had experience is the number of persons who are examining goods of all kinds with a business end in view. These inquirers come from all nations and an interpreter is not an unusual companion. Many are seeking information with the idea of taking samples abroad and making sales from them, and not a few exhibitors report some very satisfactory orders.

A Bright Sheet Among the Ternes.

After the Tin Plate Association at Pittsburgh had been disappointed in their endeavors to secure the necessary contributions to make an ideal exhibit of the industry at the World's Fair it was deemed advisable to discontinue the effort. On learning this decision, about April 14, H. T. Duff of the Irondale Iron & Tin Plate Company, urged and aided by some friends, started to secure space and material. On writing for help ten different houses responded and Mr. Duff has been able to make a very handsome showing with the material received and no doubt other additions will arrive from time to time that will make the exhibit still more interesting. The location of the exhibit in the gallery of the Mines Building is unfortunate and due to the fact that it was the only space available at the late date Mr. Duff took hold of the matter. It has been suggested that the courtesy be asked of some of the exhibitors of tinware, metal shingles, stoves and plumbing goods to hang a neat sign at some conspicuous place on their exhibit stating where the tin plate exhibit is located, so that the tinner and others interested visiting the fair may be sure to find it.

Some Interesting Experiments.

The statement that radiant heat passes directly through air without heating it, and that the latter is heated by stoves, furnaces and other heating apparatus only through its contact with the heated surfaces, has been difficult for many persons to comprehend, and, consequently, there are still to be found in the heating business those who either flatly deny the truth of the proposition, or, if they do not venture to deny it, secretly discredit it. The statement is, however, not only true, but it is important in its practical applications in the art of heating buildings, in greenhouse heating, and in other industrial arts. Some interesting experiments bearing upon this subject have recently been performed in France. Though these experiments were carried out for an entirely different purpose, they afford very striking proofs that air is not warmed by radiant heat.

Temperatures at Great Altitudes.

The experiments referred to consisted in taking the temperatures, both in and out of the direct rays of the sun, at hights of 9, and even 10 miles and upward, by means of self-registering thermometers, carried to these hights by small balloons; the hights reached by the balloons being determined by the indications of self-registering barometers. Ingenious devices for protecting the instruments when they descend from these great elevations were provided, and in the instruments employed, where metal work was required, aluminum was much used on account of its lightness. Now, by these experiments it was found that while the direct heat radiated from the sun at the hight of 10 miles is much more intense than it ever is upon the earth's surface, the temperature of the air is intensely cold, often reaching 58° below the Fahrenheit zero. This proves that the air is not warmed by the direct heat of the sun; and that the air near the earth's surface is warmed only by coming in contact with the surface itself and the objects upon it, these all being heated by the sun's direct radiant heat, that passes through the intensely cold stratum of

air above till it reaches and is partially intercepted by clouds and vapor of water at much lower hights. It has been asserted that were it not for the constant presence, even in the clearest atmosphere, of the vapor of water, the direct radiant heat of the sun would be unbearable by man, while the temperature of the air might at the same time be below the freezing point of water.

The Pig-Tin Duty.

From to-day goes into effect the duty of 4 cents a pound imposed on pig tin under the McKinley bill of 1890. As will be remembered, a bill for repealing the provision relating to this metal was presented to the last Congress and its passage was believed to be secure. In fact, an announcement to the effect that it had passed at the close of the session was erroneously made. It turned out, however, that in the hurry attendant on the closing hours of the session the measure had failed to pass the Senate, consequently the pig-tin clause stood, and has now become operative. This portion of the bill directs that a duty of 4 cents a pound shall be paid on all imported "cassiterite or black oxide of tin, and bar, block and pig tin," from July 1, 1893; the duty to be raised and the material admitted free after July 1, 1895, unless the product of the mines of the United States shall have been shown to have exceeded 5000 tons of tin in any one year prior to that date. The expectations formed for domestic tin at the time the tariff was framed have, admittedly, not been realized; and it is generally regarded as certain that the duty on pig tin will be repealed during the coming session of Congress, although matters of more paramount importance, such as the silver question, may prevent attention being devoted to the subject at any very early date. Meanwhile imports of pig tin have been unusually large this year. The following figures show approximately the receipts and consumption of the metal since January 1 last:

	Tons.
Tin in warehouses on January 1, 1893.	4,270
Arrivals to May 31	12,930
	17,200
Consumption to May 31	8,200
Tin in warehouses on June 1	9,000
To arrive during June	2,500
	11,500
Estimated consumption for June	1,500
Stocks in hand on July 1 about	10,000

Thus it will be seen that the estimated "visible" supply existing to-day in the warehouses of the United States is amply sufficient at the average rate of consumption—namely, 1500 to 1600 tons a month—for all requirements during the next six or seven months, before the end of which, it is believed, the duty will have been raised. The market for pig tin is at present in a curiously depressed condition, owing, it is said, not to any diminution in the general demand, but because of the prevailing tightness of money, preventing the purchase by dealers of more stock than they can dispose of out of hand. Prices now ruling—namely, 19.50 cents for July deliveries and 19.85 cents for August—are the lowest since last fall, and with the unusually large stocks in hand no prospect of immediate improvement is visible.

The Ferris Wheel.

Of all the engineering novelties projected in connection with the World's Fair, the Ferris wheel is the only one that has been carried to completion. The great success of the Eiffel tower at Paris, both mechanically and commercially, stimulated American inventors and engineers to attempt something equally noteworthy at Chicago. Many of these schemes have been described in our columns. One of them was the Jenison tent, with a center pole 1492 feet high and a steel and glass canopy large enough to take in the entire World's Fair exhibits. Another was the Morrison tower, in many respects resembling the Eiffel tower. A third was the Johnstone tower, 560 feet high, with an electric railroad winding about it spirally from the bottom to the top. All sorts of fantastic schemes were also exploited in the newspapers, but these were the only ones considered seriously by practical people until the Pittsburgh engineer, G. W. G. Ferris, conceived the idea of an enormous revolving wheel, with a large number of cars suspended on its periphery. It was one of the last schemes to be brought out, but it proved sufficiently practical to attract capitalists, and it was carried through.

The principle of the wheel is not a novelty, being merely the familiar revolving wheel of the summer resorts on a colossal scale. The plan upon which it is built is, however, a novelty in constructive engineering, and the daring builder is worthy of as high praise as Eiffel, who also merely advanced further than any of his predecessors in the building of towers. The construction of a great circular frame work of steel, 250 feet in diameter, so thoroughly braced as to resist any possible wind pressure, and so well balanced as to be moved easily on its axis, was a task calling for the highest mechanical ability. Further than this was the financiering of the scheme, probably more difficult to accomplish than the details of construction. Mr. Ferris has won fame in both respects. The rapidity with which the wheel was built is another triumph of his genius. Not a pound of the steel for its construction had been ordered in January last, and the foundations were not begun until well toward spring. The middle of June sees the whole work completed and in regular operation earning a revenue.

The Ferris wheel will undoubtedly be the special feature of the fair that will be vividly remembered by the millions of visitors. Even those who are too timid to venture to take a ride in one of its cars will be interested in its curious appearance and will visit its site to take a closer inspection of the greatest single piece of mechanism ever put in motion. It is a superb work and deserves to retain its place long after the memory of the exposition of 1893 has faded.

Cost of Seeing the World's Fair.

BY L. M. W.

The Centennial being frequently used for comparison, Philadelphia will be the point from which the cost is computed. This estimate is made in the interest of the wage worker and not the salaried official. Consequently luxury will not be considered, and bearing with some disagreeable things will be necessary. A ticket from Philadelphia to Chicago, good for the return trip, can be bought for $25. Now, as the journey will probably take two nights and one day, the question of eating must be considered, and a good supply of substantial provender can be brought from home in a pasteboard box, or $2 can be set down for this purpose. Where are you going to live is a question that should be decided before you leave home by writing to the Bureau of Comfort, Rand & McNally Building, Adams, Quincy and La Salle streets, Chicago, or to L. H. Lee, care of Young Men's Christian Association, 148 Madison street, inclosing a stamped envelope for an answer, and saying that you want a clean, comfortable room for $1 a day, or for as much less as a good room can be had, and there is no doubt but they can direct you to good accommodation at this figure. They will tell you how to reach the place from the station where you arrive, or a policeman will render you the same service. The same source of information will direct you to good table board, or you can find a restaurant of reasonable charges, and if you select a plain substantial bill of fare $1 a day will keep you well fed. Now, it costs 50 cents a day to get into the fair, and another 50 cents a day for car fare, incidentals and souvenirs will enable you to see all of the main and important exhibits. A walk through Midway Plaisance in the morning will let you see all that is really necessary of it.

Now, if you stay at the fair six days these last items will amount to $18, and added to the price of the ticket and lunches both going and coming it will amount to very nearly $50.

By the use of the same business judgment and foresight that you use every day at your trade or in your business you can get good plain respectable lodging and living and see one of the greatest and most interesting displays of what man, and probably only an American man, can accumulate. No matter whether you are a tinner, a plumber or any other kind of a mechanic or a clerk, it will pay you to see the World's Fair, and it is the cheapest and best education you will ever get at the price estimated, but if you want to spend more there is ample opportunity.

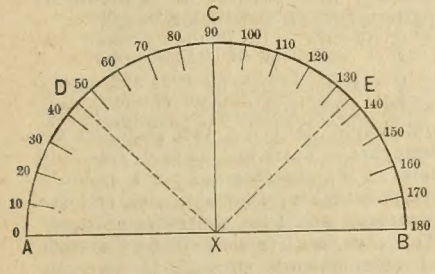
Evidence of the depressed condition of shipping business is given in the returns of transit revenues collected by the Suez Canal Company for the first four months of this year. The total receipts amounted to $4,685,966, as against $5,364,730 received in the corresponding period of 1892.

THE LETTER BOX.

Elbow Angles.

From M. A. D., *Neenah, Wis.*—I wish to inquire if there is any reason for designating elbows as they are generally listed. For instance, an elbow having an angle of 135° is indicated in list as a 45° elbow.

Answer.—The above question having been submitted to a prominent manufacturer of elbows, he replied as follows: The circumference of a circle being divided into 360 equal parts, each



Elbow Angles.—Fig. 1.—Semicircle Divided for Measuring Angles.

of these parts is called a degree. The semicircle, as shown in Fig. 1, is thus equal to 180°, and the quadrant or right angle to 90°. If the arc of a quadrant is divided into two equal parts, and a line drawn from this point to the center, we obtain one-eighth of the circle, or 45°. As 90° represents one-fourth of the circle, or a right angle, a right-angled elbow is designated as 90°. As 45° represents one-eighth of a circle, and as eight of the 135° elbows, as your correspondent calls them, placed together would represent a circle, one of the latter is designated as 45°. In the same manner, 12 elbows

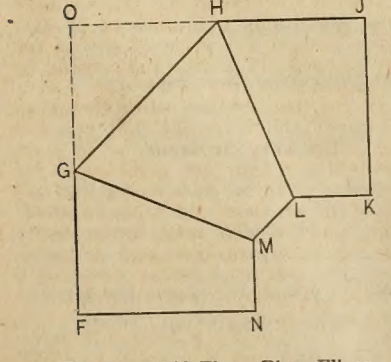


Fig. 2.—A 90° Three-Piece Elbow.

of 30°, or 16 of 22½°, would be required to form a circle. Two 45° elbows placed together would equal a right angle, or 90°. Two 22½° elbows would be equal to one of 45°, &c.

Such is the method usually adopted by the trade for designating the angles of elbows, and while it may be difficult to give a precise reason, the custom appears to be sanctioned by usage. Yet it is not the proper method, as can be seen by referring to Fig. 1. In this diagram the semicircle A C B is divided by tens into 180°. The angle formed by A X C, or C X B is a right angle, or 90°. If we bisect the right angle C X B by the straight line E X, E X B or C X E will represent an angle of 45°. If we bisect A C in a similar manner, the angles A X D or D X C are also of 45°. If an elbow was made as indicated by any of these angles, as A X D or E X B, it could be called a 45° elbow. If the elbow is made at an angle as indicated by A X E or D X B, it must be evident that the elbow is at an angle of 135°. In Fig. 2, let F G H J K L M N represent a right-angled elbow composed of the three pieces F G M N, G H L M and H J K L. It is evident the angle F O J is a right-angle, or 90°. On the other hand, an elbow having the angle indicated by F G H would be of the same angle as A X E in Fig. 1, or 135°. If 12 elbows when placed together would represent a circle, one of these elbows should be called a 150° elbow, and not a 30° elbow. Also, if 16 elbows would be equivalent to a circle, one of these elbows should be called a 157½° elbow, in place of designating it as one of 22½°.

Laying a Tin Roof.

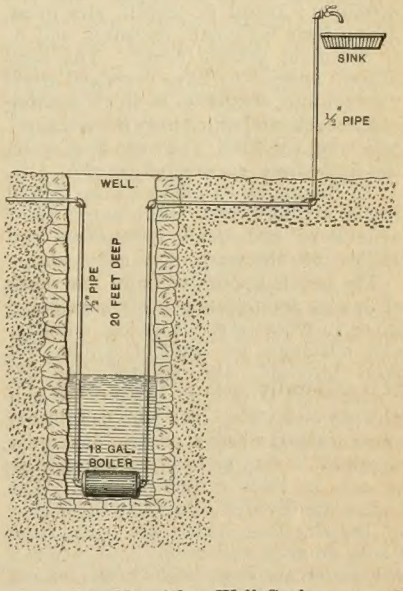
From C. S. P., *Brinkley, Ark.*—I would like to be informed regarding the proper method to use in putting on a tin roof, 50 x 80 feet, with 4 feet fall in 80, laid with flat seam and soldered. Is it best to lay the tin on roof one sheet at a time, or put it together in sections in the shop, and then lay the sections on the roof? My experience with putting tin together in long sections has been that it is difficult to get them sufficiently straight so they will lock together properly when being laid.

Answer.—When a flat seam tin roof is to be put on, we think the best results are obtained by laying it sheet by sheet, each sheet being secured to the roof boards by means of cleats. We should be pleased to have our readers give their opinions regarding the two methods mentioned by our correspondent.

Trouble with a Well Cooler

From P. R. F., *Virginia*—I did a job last summer which has not given satisfaction, and perhaps you can explain where the difficulty lies. The water mains here are not over 18 inches deep, so that in summer the water becomes very warm. I put an 18-gallon boiler in the bottom of a well and connected the supply pipe from the main to one end and ran a pipe to the sink from the other. The water, however, is as warm as if it never had run through the boiler, and I am puzzled to know why this is so. The accompanying sketch shows the general arrangement.

Note. — We have reproduced the sketch sent us by our correspondent, and will be glad to have any of our readers who may be experienced in this line tell what the trouble is. If the water is not drawn continuously from the faucet, but has ample time to cool in the 18-gallon tank down to the temperature of the well, we fail to understand why it should be so warm at the faucet. It is possible that our correspondent does not let the water run until the liquid that has been standing in the pipe between the sink and the boiler is discharged. This, of



Trouble with a Well Cooler.

course, is warmed to the temperature of the house or air. After this has been expelled, however, the cooler water from the boiler ought to flow. It is barely possible that the two pipes in the boiler may be so close together that when the water flows the warm water from the main passes through the boiler and rises in the discharge pipe without displacing the cooler water in the reservoir. This would not happen under ordinary conditions, but there is a chance that there has been some mistake in arranging the boiler connections.

The *American Shipbuilder* states that the Harlan & Hollingsworth Company of Wilmington, Del., have taken the initial step among American shipbuilders in preparing for free-trade legislation by the next Congress, by asking importers of English steel ship plates, angles and beams to quote them the lowest obtainable price for these materials laid down at their works or delivered in New York or Philadelphia.

A Jewish Trade School in New York.

Among the manual training institutions of the city of New York is one of comparatively recent date, which differs from all others now in operation here in that the instruction given is entirely gratuitous, and that the pupils are all Russian and Roumanian Jews. The school in question is a detail of the vast scheme of beneficence initiated by the eminent Hebrew philanthropist, Baron de Hirsch, to ameliorate the condition of his oppressed co-religionists from Eastern Europe who have sought shelter in the United States. This scheme includes the settling of Jewish colonies in the Argentine Republic, in Vineland, N. J., and in other parts of the American Continent, which colonization has been accomplished with more or less success.

The manual training establishment known as the Baron de Hirsch Trades Schools, was inaugurated nearly a year ago in a large building erected for the purpose at 225 East Ninth street. It is under the general direction of the Central Committee appointed to manage the Baron de Hirsch fund, of which committee ex-Judge M. S. Isaacs is president; Jacob H. Schiff, vice-president; Jesse Seligman, treasurer, and A. S Solomon, general agent. The committee appear to have exercised great wisdom and discretion in the launching of these schools, which have proved a success from the first. They are now under the immediate superintendence of Col. J. E. Bloom, an ex-officer of the United States artillery, who has brought some experience and much enthusiasm and ability into the work of management.

The pupils are drawn from the ranks of Jewish immigrants, preference being given to recent arrivals in the country, and although no limit of age has yet been imposed, the majority of the students are boys from 14 years old and upward and young men who have either never learned a trade or who have only acquired a very elementary knowledge of one in their former country. The classes are divided into two; those held in the daytime, which are open from 9 a.m. to noon and from 1 to 4 p.m., and which are composed of the element above referred to, and the evening classes, open from 7 45 to 10 p.m., which are mainly attended by young men who are occupied as helpers in their trades during the day, but who wish to improve their knowledge in them by more direct instruction during their leisure hours. It is endeavored to limit all classes so far as possible to those men and boys who have not been more than two years and a half in the country.

PLUMBING AND OTHER TRADES TAUGHT.

The trades taught include plumbing and gas fitting, artistic metal work and electro-plating, sign and fresco painting, machinists' work and mechanical drawing, carpentry and wood turning and wood carving. Each class has either one or two instructors, those for the day classes usually assisting the evening teachers, who are otherwise occupied during the day, and who generally give instruction in the more advanced stages of work, their pupils having, as a rule, already mastered the elementary principles of their trades. The plumbing and gas-fitting classes, both day and night, are, however, under the care of a permanent instructor, B. Bedanes, a graduate of the 1885 class in the New York Trades School. The average attendance at both these classes is from 16 to 20, the number of students being limited to the latter figure on account of restricted accommodation. The evening class in plumbing might easily be multiplied by three or four, we are told, did considerations of space not forbid. The work done by the beginners in the day class is very creditable to their instructor, who states that it is surprising how quickly these Jewish lads, who have often never seen any plumbing work in their lives, pick up the use of the soldering iron. They can, it is said, learn to make a seam or wipe a joint in much less time than is generally taken in mastering the operation by their Gentile brethren. Instruction is given on essentially similar lines to those used in what is known as the Auchmuty system, as practiced in the New York Trades School. Indeed the whole organization is founded upon the excellent principles made use of in that successful institution.

The sheet-metal class is mainly instructed in the production of small fancy objects in brass and copper, many of which are very beautiful in design and execution, approaching to jewelers' work. A very attractive exhibit of the work done in this class has been sent to the World's Fair.

Carpentry and wood turning is a very favorite branch of study with the Hebrew immigrants. Many of the articles of household use produced by them are used in the de Hirsch colony at Vineland. The classes for sign and fresco painting are also well attended, and no difficulty has yet been experienced in keeping all the departments of instruction full of pupils. In fact the managers are in a quandary as to the provision of sufficient space to accommodate all the deserving applicants for a place in the schools. At present they are obliged to exercise their discrimination in the matter.

GENERAL ARRANGEMENTS.

The course of instruction in all trades is nominally six months, but certificates are granted to men who show the necessary proficiency after as short a period of study as three or four months. The certificates issued are merely recommendations stating that the bearer has had so many months' instruction at the schools and is recommended as a diligent worker, the form being as follows:

BARON DE HIRSCH TRADE SCHOOLS.

No..... 225 East Ninth street, New York.....

THIS IS TO CERTIFY *that the bearer*.....

aged..... *years, has had*..... *months' instruction*.....

in our department of.....

He is especially competent in.....

.....

We recommend him as a diligent, faithful worker. If you give him a trial, please report to us his progress and deportment from time to time.

Yours truly,

....

Instructor. *Manager.*

N. B.—If the bearer is not acceptable, kindly return this certificate with indorsement, stating your requirements—either in this or other department.

During the first year's existence of the institution these recommendations have been given to 58 graduates who, we understand, have all secured lucrative employment, many of them in distant cities.

It is the aim of the management to locate their students so far as possible outside the city of New York, in places where the labor market is not overstocked, so as not to compete with the large demand for employment existing here. In this way they believe they can benefit both the men and the country at large by providing capable workmen to establishments situated in places where skilled labor is not easily obtained, especially in the newer portions of the Western States.

Another object which Colonel Bloom has in view is the teaching of American methods of work to those Jewish immigrants who have learnt a trade in their former country, but who find its conditions here to vary from the practice they have been accustomed to. This, it is believed, can be done in a very short space of time.

A labor employment bureau is also in contemplation in connection with the schools, and other additions and improvements, including classes in house painting and papering, boot and shoe making, and possibly in sheet-metal pattern cutting and tinners' work.

SYSTEM OF MARKS.

A system of marks is in operation which gives a standard of ten marks obtainable daily by the pupil in all branches. These are made up as follows: 5 for character of work done, 2 for punctuality, 2 for attention and deportment, and 1 for general cleanliness. This plan, with a very efficient system of office records showing the particulars of each individual and the work done by him, was arranged by Colonel Bloom, and has just been adopted.

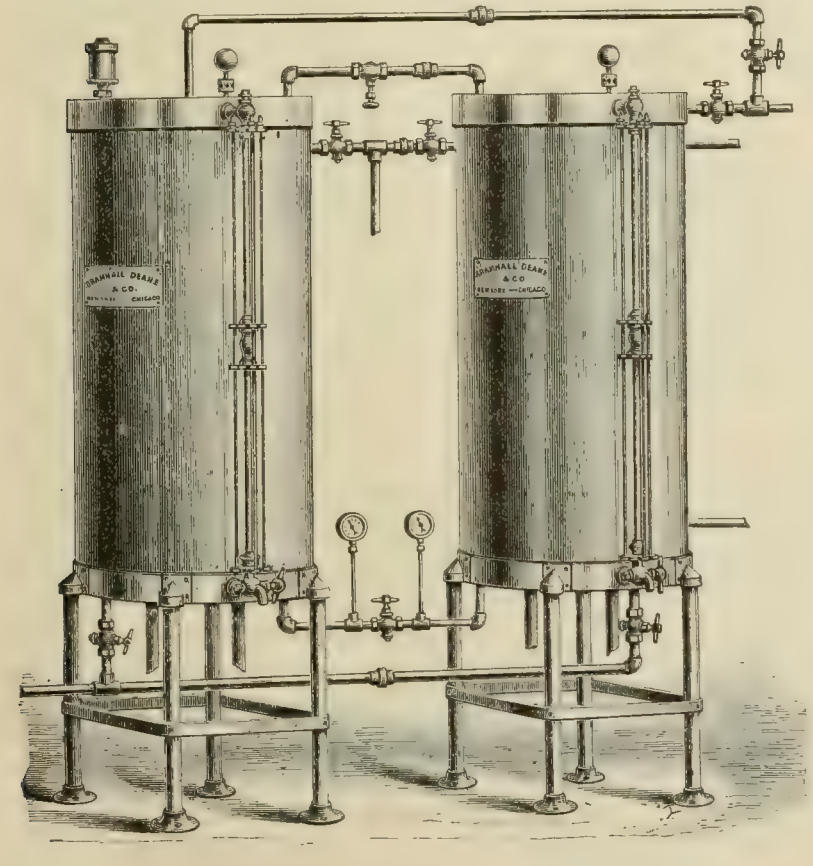
One great disadvantage under which the newly-arrived scholars generally labor is their total ignorance of the English language. Most of the instructors are, however, able to communicate with them in their own tongue, and the pupils of the day classes—who are the only ones so situated—are obliged to attend the evening classes for the study of English at the Hebrew Institute on Broadway. No man is given a certificate from the school until he has a competent knowledge of the English language. The manager says that most of them pick it up in an astonishingly short space of time.

The poorer boys, who have no friends or means of support in this country during their term of pupilage, are sheltered at a lodging-house, also under the direction of the Baron de Hirsch fund. Here they are housed, fed and clothed gratuitously, and at the end of their term are, like all the other graduates, found employment which will make them self supporting.

LECTURES.

Every Saturday evening a lecture of some sort is given on some interesting or instructive mechanical or trade subject. Occasionally literary or musical entertainments with stereopticon views are provided. For the benefit of newcomers, ignorant of English, the lecture is sometimes interpreted into Russian. Some able speakers have been secured for this purpose, and this feature is much appreciated. On the first Saturday in June Col. A. S. Bacon spoke to the pupils about the West, and the advantages offered by that part of the country to steady men and skilled workers.

The courses commence the first Monday in each month the year round. New pupils are then received, and started on their term of from three to six months, according to the progress in proficiency which they display.



Apparatus for Automatically Sterilizing Water.

Water Sterilizing Apparatus.

Bramhall, Deane & Co., 262–266 Water street, New York, are manufacturing several forms of sterilizing apparatus, one of which is here illustrated. This device is designed for sterilizing water for drinking, cooking and surgical purposes. It may be used with steam or gas and can be made either portable or stationary. It automatically sterilizes water under pressure, giving any required temperature, and makes it practicable to draw sterilized water for use without exposing it to contact with unsterilized air. The materials used in its construction may be of copper, composition or non-corrosive metals, and nickeled or silver plated. The smaller apparatus have appliances for being heated with gas. Those of large capacity are arranged to receive steam generated elsewhere for sterilizing. The cut shown represents apparatus of 100 gallons capacity. The cylinder at the left has an interior steam coil, which is surrounded by the water (which has first been filtered) to be sterilized. After being sterilized it is forced under pressure into the tank at the right, where it is cooled. Connections are made enabling the user to draw hot, cold or tempered sterilized water at any point to which pipes have been laid, or at the faucets shown in the cut. The customary water and pressure gauges, safety valves, tell tales, &c., are attached, as well as an overflow to prevent any excess in the sterilizing tank. Bramhall, Deane & Co. are manufacturing several other styles of apparatus for sterilizing bandages, dressings and instruments for use with steam, gas or lamp, suitable for private practice, hospitals or other institutions.

Notes from Indiana.

THE BRUCE & MARKS MFG. COMPANY,

Gas City, Ind., recently started their plant at work making grass hooks, which they are now turning out at the rate of 1000 a day, though their capacity will be more than double this when the whole plant is in operation and all the machinery and hammers are set up. Their steel comes to them rolled in special shapes, from which their patented hooks are made. Hay and corn knives will be added to their productions as the season advances. Chas. H. Marks attends the manufacturing, having had many years of experience with the implement makers at Auburn, N. Y.

THE WESTERN BRASS COMPANY

of Gas City are just getting to work in a new plant for making gas fixtures, chandeliers and brass fittings. This is a branch of their works at Bridgeport, Conn., and Whitehall, Mich., and the line of goods made in Gas City will be principally for gaslighting.

MOREWOOD & CO.

The erection of their tin-plate manufacturing plant at Gas City has been very much delayed by the weather which prevented their railroad siding being run in and so prevented them getting materials. The buildings, however, are now all up and the tinning stacks also. The size of the buildings, the number of them and the space they cover all indicate a large producing capacity and show that experienced judgment was displayed in their arrangement. No undue haste is being used in getting into operation, but as the machinery is now arriving and being set up it is fair to suppose they will be ready for early fall trade.

THE ELWOOD IRON WORKS,

Elwood, Ind., have two plants, the one on the north side being new, and is just about starting to make radiators for the Holland Radiator Company of Chicago. The older plant consists of a foundry and machine shop, where they make gate valves and fittings for natural gas work, and has been considerably occupied in making annealing boxes for black sheets for the tin plate plants, an improved tinning machine for both bright and terne plates, a cleaning machine for running the coated plates through bran and a duster to remove anything from the coated surface before it is sorted and boxed.

THE AMERICAN TIN-PLATE COMPANY.

Another tinning stack has just been put in operation at Elwood, and in order to turn out the black sheets faster a mill to roll the billets to tin-plate bars is now ready to start, and a furnace for heating the billets is ready for use. The superintendent, W. H. Banfield, is more than pleased with his improvement in the tin plate mills, which has increased their capacity.

THE AKRON FORGE COMPANY

of Akron, Ohio, have just broken ground at Elwood for a branch of their works. The building is to be 70 x 240 feet, and will be pushed to an early completion to get the benefit of gas.

THE INDIANA TIN-PLATE COMPANY,

Atlanta, Ind., enjoy a supremacy in manufacturing, being the only plant in that town to attract wide attention. Under the experienced supervision of Enoch Stanford, the plant is running in a conservative and satisfactory way. They were annoyed recently by the tank of one of their tinning machines cracking, which necessitated the delay incidental to putting another new stack at work.

THE PERFECTION MFG. & SUPPLY COMPANY,

at Tipton, do a general foundry and machine business, but make a specialty of a straightway, quick opening valve for natural gas. These valves are called on to stand a gas pressure of 350 pounds to the square inch in use, and in some sections the pressure has been as high as 500 pounds, but so high a pressure seldom continues.

Lord Thurlow, chairman of the Harney Peak Tin Mining Company, is reported to have said that operations will be resumed at the mines by October 1.

PLUMBING and GAS FITTING.

Plumbers' Examination.

From P. J. R., *New York.*—Having a job in New York I am receiving quite a number of letters from friends that I have made among the plumbers while working in different parts of the country, asking me to send them the questions used by the Examining Board in New York, according to the new law that is now in effect. As there were so many I concluded I would send my letter to *The Metal Worker*, dropping them a postal to watch for it; and if they are disappointed in never seeing it, it will not be because I never wrote it. The examiners are good practical plumbers, and have too much good judgment to adopt a series of questions that some fellow would give away, so that answers could be got and enable the very ones to pass who ought to be weeded out. The examiners render the citizens a very efficient service, and yet are just in the plan they follow. The questions are many and rigid, or few and leading, according to the ability, acquaintance with the subject and general knowledge a man displays in his answers. The plumbers in any neighborhood can greatly benefit themselves if they will all meet, bosses and apprentices, some evening, and select three judges who shall ask questions that may be answered by any one in the meeting, not allowing over five minutes to a subject. Questions like these might be asked, and would prove of interest to all:

How should a double boiler be connected?

What descent should a sewer pipe have?

Where and how should the main sewer be tapped, to connect a drain?

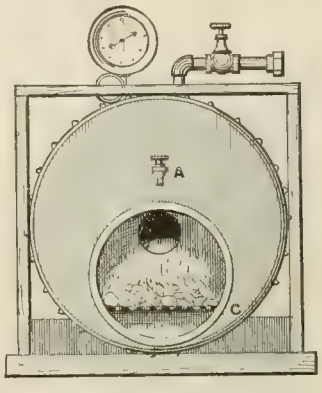
Where would you start to plumb a building?

From the answers a plumber would make to such questions a good idea of his ability could be determined by a committee of practical working plumbers, whether appointed by law or selected by friends, and much valuable information could be acquired by the boys. Such a meeting would be very similar to the examinations in any city under the new law, and if followed up with a lively interest would be of use to all concerned.

Thawing Frozen Street Mains.

There was printed in *The Metal Worker* of April 1 a communication from "S. I. D.," Canada, describing his method of thawing frozen street mains. Another correspondent writes us later, asking if he could not obtain a description of the boiler used for the purpose. We have in reply to this inquiry the following communication from "S. I. D.:"

There are quite a number of different kinds of boilers that can be made from sheet iron for the purpose. Before the plumbers' gasoline furnace came into use I made one like the old fashioned Cornish boiler, with fire hole surrounded by water, in which we burned charcoal, wood chips, &c. It was made cylindrical, as shown in Fig. 1, about 10 inches in diameter and 8 inches deep. A is a ¼-inch pet cock, from which we could tell the hight of the water in the boiler. A ¼-inch globe valve was placed in the pipe to shut off the steam. C was a grate made of wire netting of about ½-inch mesh. A door was placed in front of the fire hole and a 2-inch smoke stack, which is not shown in the illustration, was provided. It was mounted on a



Thawing Frozen Street Mains.—Fig. 1.—*Section through Horizontal Boiler.*

base and cased with ⅛-inch hardwood, as shown, to protect it from injury.

This was all very well when we had nothing better, but it was much more convenient to use a gasoline furnace, and I will try and show how to make a boiler for use in connection with one. It is the simplest kind I know of, and will answer the purpose effectually. Take a piece of galvanized iron, No. 18, 10 x 20 inches, and form it into a cylinder, giving about 1 inch lap for

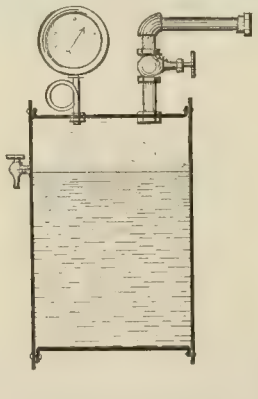


Fig. 2.—*Section through Vertical Boiler.*

seam, which must be riveted closely. This would be about 6 inches in diameter when formed up, and 10 inches high. Make the ends 4¾ inches in diameter, and turn up 1 inch all around, as shown in Fig. 2. Fasten a ⅜-inch nipple in top of the boiler by means of two lock nuts, as shown, for the steam pipe, and repeat the process for a steam gauge. Place another in the side, about 2 inches from the top, for a pet cock, which is used for filling the boiler, as well as for blowing off the steam, &c. The ends of the boiler are riveted in, as shown, and after that all the seams are heavily soldered. A ¼-inch globe valve is placed on the steam pipe, pretty close to the boiler, with a nipple and elbow for making connections by means of a union with a ¼ inch coil of lead pipe. A very low pressure is sufficient to thaw out most pipes, as they are frozen in a great many cases where they pass through a stone wall, and this is a place difficult to reach by any other method than that described in *The Metal Worker* of April 1. Fill the boiler with water by taking out the pet cock in front, and use a funnel with a tube at the end bent sideways. When the water level is up to the hole screw in the pet cock again, and set the boiler on top of the furnace, which will soon give enough heat for the purpose. I made other kinds of boilers, which would heat quicker, but were, of course, harder and more expensive to make. In this one there are very few joints, and consequently it is more durable.

Note.—The above is an interesting account of an apparatus for thawing frozen pipe, but it must be borne in mind that a home-made boiler of this kind is not adapted to high steam pressure, and it must be used with care. If the pressure rises above a very small amount it will not do to keep the valves shut. We think our correspondent would have done well to provide his home-made boiler with a safety valve to blow off at low pressure. Steam is a dangerous thing to handle, unless provision is made for its escape in case of too great strain on the boiler. Bearing this point in mind, however, we think that the description of boiler shown may be of service to many in the plumbing trade.

The Management of Office and Shop.*

BY ALFRED HOPKINS, BRIDGEPORT, CONN.

What I have to say regarding the management of the workshop, salesroom and office will be only a brief outline of suggestions. Some of these suggestions will be reiterations of time-worn remarks, but as "keeping everlastingly at it" has done wonders in the past, I believe it to be a potent factor in the elimination of evils of the present.

To contrast order and chaos, well lighted premises and dingy apartments, cleanliness and dirt-encumbered floors and counters, is not my intent. If there are any in our craft who cannot see the advantages possessed by the first named of each of the conditions contrasted it would be far from my desire to effect a change. Nothing short of the millenium itself would be capable of doing anything like that.

Of the treatment of workmen in one's employ, the less said the better, since the individual peculiarities of persons are so dissimilar that no set rules can be laid down for general guidance. A quiet determination gives by far the best results. It is to be

* Presented at the Milwaukee convention of the National Association of Master Plumbers.

borne in mind, however, that politeness on the part of both the employer and the employee is to be encouraged, but beyond that politeness, all which tends to make undue familiarity is to be avoided. While it is well, of course, to have the good opinion of all those in one's employ, it is also desirable to remember that a master who is too easy in his methods of discipline is likely to have as little work done as the hard task master who is unnecessarily harsh. Like all things else, there is a medium between the extremes.

Where a foreman is employed he should be given entire charge of the work over which he is placed, and should be held strictly accountable for the quality of that work. If not, what is the use of having a foreman? Would his salary not be a dead loss?

The slip-charge method, which consists in the employee writing on a slip and giving it to the man at the office for the materials used on each job he works upon, is the best known method of preventing troublesome differences between the customer and one's self. Where more than one day is put upon a job, all material used the second or subsequent days is to be entered upon another slip and properly dated and signed with the initials of the workman, when the job is completed, all material returned to the shop is to be credited upon a similar slip (but of different color), and the result of the slips figured and added in a book for the purpose, is the easiest mode of proving material used which has ever come to my notice.

The time is to be disposed of in the same way, except that one day each week, preferably Friday, the workman wait after hours a few moments and give in the time spent on the different jobs for the previous week, and this is entered upon a time book, which keeps a separate account with each man, and besides saving delay on pay day, it is a certain preventive of paying for time not given by the workman, for only what time he accounts for is credited to the account of the man on the time book and no danger is experienced of being unfair.

The forgetfulness of workmen in failing to ask for material needed until the very moment it is required is annoying in the extreme. It can be avoided by compelling each man to write out a list of stock required for his next day's work which is not in the shop. The failure of the workman to do this results in his being laid off until the stock arrives. Once doing this is usually enough to sharpen his memory.

The importance—particularly with new and prospective customers—of a clean salesroom and neatly dressed salesmen cannot be overestimated, and their importance toward the general summary of business prosperity the merchant cannot afford to overlook.

Another point is the having in sight and in form for operation the various devices to be sold. Illustrated catalogues are for old-timers. The device itself and in operation is the modern way of doing business. The device may be on hand, but if dust covered and generally unattractive the sale drops through.

Our traveling salesmen will bear witness that a clean office is a certain sign of commercial prosperity; 50 years ago one did not mind a little dirt in a corner of a shop where the books were "kept," but to-day, the customer may be stylishly dressed and in light fabrics, and wants a clean office floor and unobstructed chair while he talks business. A file of latest catalogues and price-lists in order and at a convenient place adds wonderfully to the force of an argument with a customer.

The longer the interval between the completion of work and the sending of a statement of the same, the more likelihood of differences and consequent loss of custom. By sending a statement at once, alleged errors can be straightened out and general harmony prevail. The sending of such a statement should not be taken to mean a "dun," but merely for the purpose which is attained when a manufacturer sends a shipping statement. Attention to this detail may mean hundreds or even thousands of dollars in one's pocketbook.

I might go on indefinitely giving these little suggestions, but with one more I shall close. What I wish to impress upon the minds of the craft is that the lavish use of a letter copying press never did any harm and yearly does untold good. A copy of a letter takes no room in a letter book; a contract is easily copied, and if even in ten years after it is brought into question, the law has decided a letter copy made by sympathetic ink to be "original evidence" when the letter itself is missing. Great pecuniary loss often results from failure to use a copying press.

TRAPS AND VENTS.

FRED ADEE & CO., 90 Beekman street, New York, are putting on the market the Duplex water closet, which they describe as a combination of the best features of the Capital and A.D. They say it will work well if the cistern is placed any hight, from 3 to 7 feet above the closet, and if the flush pipe, which should be 1½ inches, is straight, or made with elbows or flush bends, 1 or 6 feet. Its noiselessness is a special feature referred to.

NOTICES HAVE BEEN ISSUED to the trade stating that the Mercer Pottery Company, Trenton, N. J., have purchased the business of the Beekman Salutary System of New York, and the Smith & Anthony Stove Company have been made their sales agents. The latter firm have a large and spacious store at 56 Beekman street, New York, where they exhibit the Beekman whirlpool wash-out closet along with their Sanitas specialties and other plumbing supplies.

MAYOR WHELAN of Troy, N. Y., has appointed as members of the board of examining plumbers of that city William Ferguson, Martin Mulligan and Michael J. Flannery. They will soon proceed to examine the plumbers of that city.

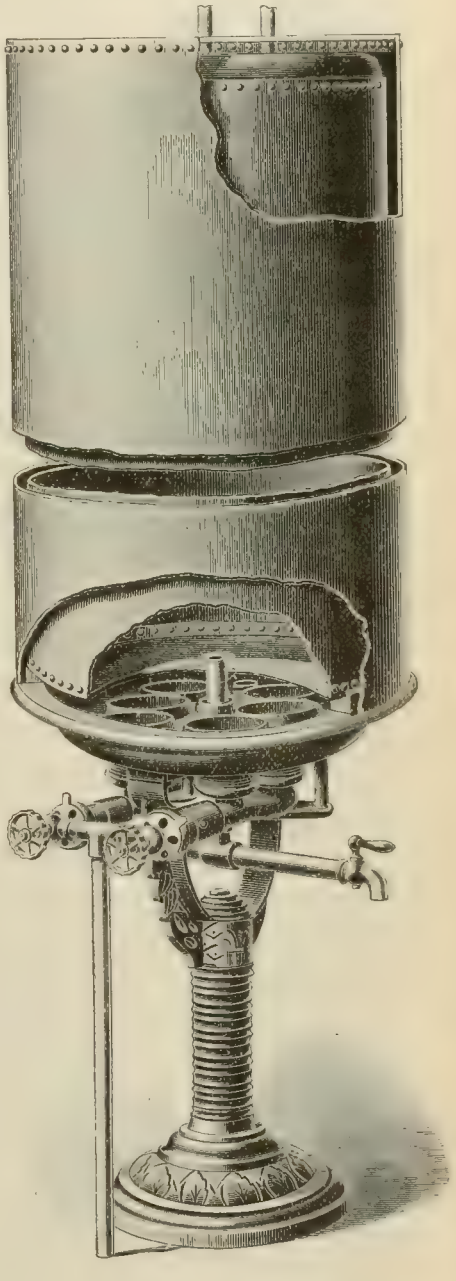
THE NEW JERSEY LAMP & BRONZE WORKS, New Brunswick, N. J., have ready for distribution to the plumbing trade a new catalogue of gas fixtures which is a fine example of artistic printing.

TWO YEARS AGO last May a new manufacturing enterprise was started at Buchanan, Va., known as the Smith & Briggs Brass Works. This was an amalgamation of two former Brooklyn, N. Y., interests, transplanted to Virginia on account of inducements offered by communities and land companies. The company now have in operation a foundry, 80 x 30 feet in dimensions; brick building for engine, 40 x 40 feet; a polishing room, 40 x 40 feet, together with a finishing department, 100 x 30 feet. There is also a pattern shop, 50 x 25 feet, constructed of iron, besides a core room, blacksmith's shop, coal sheds and pump house. They manufacture principally bathroom and lavatory fittings, Handy wash tray and waste traps, stop cocks and plumbers' brass work generally, as well as specialties from composition, phospho-bronze and aluminum. This plant is located on the Norfolk & Western and Chesapeake & Ohio railroads, and the Baltimore & Ohio Railroad will soon be in there. Coal is cheap and labor is advantageously secured. The force at present numbers upward of 40 hands. The New York office is at 275 Pearl street, where a stock is carried. The president of the company is Benjamin C. Smith, who also does a general plumbers' supply business at the above address, independent of this interest at Buchanan. The works are in charge of William Briggs as manager.

JOHN T. MCMAHON, a Harlem plumber, has been appointed deputy-warden of the Tombs, New York City.

Gas Heated Kitchen Boiler.

The Gilbert & Barker Mfg. Company, New York office 90 John street, are offering a device as here shown for heating water. This is designed for use where the ordinary range with water back is not available, or where, during the warm months, it is not desirable to operate a range; also, if for any reason the range when in use is not equal to the requirements this may be used exclusively or in connection with the range. It will be readily seen that the most economical way to heat water is to maintain a fire under it.



Gas-Heated Range Boiler.

This is not only accomplished, but the boiler is kept surrounded by a bath of hot air that has already been utilized below, by means of a sheet-iron jacket placed around the boiler. The boiler support is a cast iron bed plate with six round holes about 3 inches in diameter, conforming to the shape of the burners, thus insuring a constant and uniform supply of outside air to assist combustion, in addition to the customary air mixers attached to both gangs of burners. Each set of three burners is controlled by a valve, so that one or both may be used. The heat can be kept at a minimum or maximum, started or discontinued in a moment. The company are not only installing this apparatus in connection with new work, but are applying it to ordinary house boilers already in use. One feature referred to is that in case of drip from any cause whatever, it would be caught in the cast-iron stand and evaporated at once. The immunity from handling of wood, coal and ashes is likewise dwelt on by the makers

THE ST. JOSEPH PUMP COMPANY, St. Joseph, Mo., are making an addition to their already extensive plant. The addition referred to will be a two-story brick building, 35 x 90 feet. This addition has been necessitated by the fact that the company have outgrown their present capacity, and the new building will be entirely utilized as soon as it is finished. E. A. King, secretary and general manager, has been with the company from the start, and much of the success attained by them is due to his efforts.

THE BOSTON PLUMBERS adopted this week resolutions thanking the members of both branches of the Massachusetts Legislature who supported the bill relating to sanitary plumbing and providing for the registration of plumbers.

Worthy of Imitation.

About a dozen of the young men employed in the machine shops of M. C. Hammett at Troy, N. Y., decided about two years ago that a knowledge of drafting and geometry would be of benefit to them in their business. They laid the matter before their superintendent, W. S. Rogers, and found that he was heartily in sympathy with their movement and at their request agreed to give one evening of his time every week in giving them lessons, but their employer, also desirious that they should have every facility for furthering their plans, offered the free use of office and drawing room, light and materials. The result is that one of them to-day holds the position of superintendent for a new and growing firm, another is foreman in a large machine works in a Southern city, a third is an inspector in a large electrical manufacturing company in Massachusetts, one of them has been raised to a position of trust by his employer, another, having finished his term of apprenticeship, is fitting himself for a course in the Rensselaer Polytechnic Institute at Troy, while the youngest, after serving another year in the shop, will also take an institute course. These six young men had two years ago only ordinary prospects of employment. Their efforts have proved their benefactors. The remnant of the class gathered at Mr. Rogers' house a few evenings since to take their final lesson and recieve their diplomas. The young men presented their superintendent with a handsome silver smoking set.

Prize Competitions

$25.00.

As announced in previous issues the following competition is now before our readers and remains open until the date named:

Prize Competition No. 27.

SUBJECT:

Local Associations of Merchants.

It has been found feasible to form associations in many places for the purpose of securing more friendly relations among competitors and reaching an understanding in regard to matters of common interest. Among the good results referred to as coming from such associations are the following: Overcoming petty jealousies; cultivating a spirit of fraternity; listing of undesirable customers; an understanding in regard to time of presenting bills; putting in operation early-closing movements; agreement as to the prices at which goods are to be sold; mutual accommodation in supplying goods which one merchant may be temporarily short of, &c. The subject is thus evidently a broad one and of a good deal of practical interest. In discussing it the following points are suggested:

Whether it is desirable to have such associations;

How such associations may be organized;

The objects to be accomplished by them.

It will also be of interest to have any information in regard to the practical working of such associations.

This competition will remain open until July 8, 1893.

The following prizes will be awarded in each competition:

First prize.....	$12.50
Second prize.....	7.50
Third prize.....	5.00

The prizes will be awarded for answers which, in the judgment of the Committee of Award, are most suitable for publication and of the most general interest

We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than the dates on which the competitions close. They should be addressed as follows:

DAVID WILLIAMS,
96–102 *Reade street,*
New York.

Building Ordinances of Berlin.

The European correspondent of a Baltimore journal, writing from Berlin, gives some particulars relating to the building regulations of that city which show that a military discipline, characteristically German, exists in the municipal government of the metropolis of the Fatherland. He expresses himself as follows: "Berlin is the best managed city in the world, and its city fathers regulate the style of the buildings which shall be put up. You can't build a dog kennel without showing a design of it at the City Hall, and no man can put up a sign-board on his own house until he has shown a diagram of it and has gotten the permission of the government. You can't put down a pavement in front of your house without a permit; and the government watches your building and insists that you make your walls just so thick, while the ceilings must be of a given hight and the fronts must be of a uniform pattern. In building the house you are not allowed to litter the street with your brick and mortar, and all the materials must be kept inside the lot. You have to fence off the street while the building is going on, and when your house has reached the hight of the second story you must build a roof over the sidewalk to prevent the bricks or mortar falling on those passing below. The building is done much better than with us, and much more economically. Nearly all the mortar is mixed at one place, there being a mortar company which sells the material ready mixed to the builders and carries it about in iron wagons and delivers it just where it is needed. This Berlin establishment is paying dividends of 25 per cent. on its capital, and it sells mortar, like coal, at so much per wagon load or per ton." In regard to the latter subject, the writer was evidently unaware that a similar system of mortar supply was already in operation in this country, having been introduced in the city of Philadelphia last year with the best results.

The latest project in ship canals is one to connect the city of Brussels with the sea. The Belgian Government has decided to contribute a round sum toward the work. It is also willing to take over shares of the company to the extent of $1,200,000 and to guarantee the obligations of the concern.

In 1892 there were granted a total of 3417 Canadian patents, of which 2227 were taken by American citizens, 671 by Canadians, 298 by Englishmen, 106 by Germans, 26 by Frenchmen and 89 by persons of other nationalities. It will thus be seen that nearly two-thirds of all the patents granted in Canada are to American inventors, and but for them the Canadian Patent Office would make a very poor showing. The entire receipts of the Canadian Patent Office were $84,720, and the expenditure was $39,643, leaving a profit of $45,000 over expenses. It may be said that American inventors chiefly support the Canadian Patent Office as well as the Patent Bureau at Washington.

The New York Academy of Medicine's special committee on quarantine precautions has drafted a bill for the establishment of a national quarantine, which would have supreme control of the quarantine in all ports, thus removing this important matter from the influence of local politics. The committee is anxious to have this measure presented to Congress with the indorsement of the entire medical faculty of the country.

The German Society of Engineers has issued a circular soliciting subscriptions for a proposed memorial to the late Werner von Siemens.

TIN PLATES.

Tin Plate Production to March 31.

Colonel Ayer's report on the production of domestic tin and terne plates during the first quarter of 1893 not being yet forthcoming from the Treasury Department, a Pittsburgh journal—*Tin and Terne*—has compiled an interesting summary, based on reports obtained from 24 firms engaged in the manufacture, which indicates that the increase in production of domestic tin plates during the months of January, February and March approximates 36 per cent. more than that of the last quarter for which we have the official returns—namely, that ending December 31 last, notwithstanding that manufacture had been more irregular at some of the works. The figures given by these concerns, which include two-thirds of the whole number of tin-plate works now in operation, are tabulated as follows:

	Lighter than 63 lbs. per 100 sq. feet.	Heavier than 63 lbs. per 100 sq. feet.
	Pounds.	Pounds.
Tin plates	12,929,129¾	417,703
Terne plates	10,502,556½	.....
Total	23,431,686¼	417,703
Made from American black sheets	8,950,826	
Made from imported black sheets	12,310,165	
Total	21,260,991	

When it is understood that the 12 or 13 producing concerns from whom no reports were collected include in their number some of the largest in the country, the assumption that at least 32,000,000 pounds will represent the total production of tin and terne plates for the quarter appears to be a conservative conclusion.

The Tin-Plate Exhibit.

In the Mines Building at the World's Fair, on the second floor at the south end, is found the display made by the American tin and terne plate manufacturers. Here all of the materials that enter into the production of tin plate are shown. There is the fuel used (no natural gas, of course), both coke and coal, with the pig iron, which becomes a billet, and next a tin-plate bar, then rolled into sheets of less and less thickness until the lightest black plate is shown, cleaned, ready for the plating of either lead for ternes or tin for bright sheets. A big glass bottle shows the palm oil, and a pile of brown dirt shows the tin as it comes from some mines, and a lot of stones or quartz rock shows the ore of other mines. Then the smelter is shown, with pigs of tin from the Temescal mines in California and Harney Peak mines in South Dakota. Lead ore and pigs of lead are also exhibited. Grouped around this display are boxes of both bright and leaded plates from the many tin-plate plants in this country, and that the piles of boxes are no higher is due to the demand for every sheet made.

The skill of the American tinner has been called in use to make the display complete by inclosing the space with an ornamental railing and balusters made of tin, and three pavilions, to show the elaborate effects possible with tin in columns, cornices, ceilings, walls and roofs. On a tin pedestal at one side is a glass case containing a full-rigged schooner made entirely of tin, and on the other side on a similar pedestal rests a column at the top of which is a globe with an eagle perched upon it holding a banner in its beak, the ends of which are attached to its outstretched wings, all made of American tin plate. This exhibit is in the charge of a gentleman connected with one of the large tin-plate plants, and who answers the many odd questions asked by the always inquisitive sightseers.

The following is a list of the makers who have contributed to make up the exhibit: American Tin Plate Company, Elwood, Ind.; Irondale Iron & Tin Plate Company, Irondale, Ohio; St. Louis Stamping Company, St. Louis, Mo.; U. S. Iron & Tin Plate Company, Demmler, Pa.; Columbia Tin Plate Company, Piqua, Ohio; Cincinnati Corrugating Company, Cincinnati, Ohio; Cleveland Tin Plate Company, Cleveland, Ohio; Marshall Bros., Philadelphia, Pa.; Phillips Bros., Philadelphia, Pa.; E. Morewood & Co., Elizabethport, N. J., and Gas City, Ind.

SCRAP.

A LOCAL PAPER of Pennsylvania origin makes the astounding statement, on the authority of a prominent manufacturer, that "this country consumes about 400,000 tons of tin plate daily." This is equivalent to nearly 3000 millions of boxes a year. If the reporter had written *yearly* instead of daily in the sentence he would probably have quoted his authority correctly.

THE STRIKE at the Carmarthen Tin Plate Works, Wales, has been raised by mutual concessions on the part of employers and employed.

THE BRITISH tin-plate market is reported as unchanged in its dullness. Advices from London, under date of June 17, are to the following effect: There is very little life in things here, and the outlook for the next few months does not look hopeful. There is not much business offering, and what there is is eagerly sought after by sellers, and prices are again a shade weaker, some good orders for cross specifications having been placed at lower prices than had ever been accepted before.

THE ALIQUIPPA TIN PLATE COMPANY'S plant at Aliquippa, Pa., has been shut down temporarily, but will be started again about the middle of July.

LYON, CONKLIN & Co. of Baltimore, report a large demand for their roofing plates, particularly for their brands known as Lyon Hand Coated and L. C. & Co.'s Redipped, and for their single-coated roofing plate known as the Glendale brand. This is very satisfactory to the firm and speaks well for their goods.

AN ENGLISH TRADE JOURNAL, in writing recently about the American tin-plate industry, remarked that the fact had long been patent "that, in the way of manufacturing tin plates America is capable of doing practically nothing, at present at any rate." Our contemporary's information must be somewhat incomplete; or perhaps its statistics were taken from the source from which so many English papers have of late drawn their material for articles on the tin-plate manufacture of America—namely, the report of the British Secretary of Legation at Washington, which was published a couple of months ago. The figures there given are those for the half year ending June 30, 1892. Twelve months of vigorous development since that date have put a different complexion on the matter.

A Prehistoric Blast Furnace.

Prof. Flinders Petrie, the distinguished explorer of biblical lands, when excavating and investigating in Southern Palestine a few years ago convinced himself that in a remarkable mound called Tel-El-Hesy would be found the remains of what was one of the strongest places in that country down to the invasions of Sennacherib and Nebuchadnezzar. The explorations since carried out on the spot were announced at a recent meeting of the Palestine Exploration Fund in London as having fully verified this forecast. The mound is found to be composed of no fewer than eight successive towns formed on the ruins of one another, the uppermost dating about 500 B.C. and the lowest, or earliest going back to 1500 B.C., the time of the great Egyptian conquests in Palestine. Amid all the evidence discovered by F. J. Bliss of the American College at Beirut, Syria, who has had charge of the excavations, of the civilization of that remote age—wine presses, treacle presses, alkali burnings and innumerable other things—by far the most curious is the disclosure of an iron blast furnace, so arranged as to give strong evidence of being intended to heat in its descent a blast of outside air forced through passages before entering the chamber at the level where tuyeres are usually found. "If my theory be correct," says Mr. Bliss, "we find 1400 years before Christ the use of the hot-air blast instead of cold air, which is called a modern improvement in iron manufacture due to Neilson, and patented in 1828."

The following changes in the rates of import duty levied on the undermentioned articles have been introduced by the Newfoundland Government: Iron and steel buildings (not including their wood work) iron and steel beams, girders, joists, pillars, columns, doors, sashes, shutters, cornices, architraves, channels, gutters, angles, structural shapes, shingles of iron, steel or composition; sewing machines, knitting machines, and parts of same, are now all assessed at 10 per cent. ad valorem.

ROOFING AND CORNICE.

Laying Steel Roofing.—III.*

BY L. S. BONBRAKE.

FIRE WALL AND CHIMNEY FLASHING.

Perfect fire wall and chimney flashing is important in the construction of a metal roof, and is secured only by counterflashing or the use of a strong, durable cement, as Portland or rock plaster. In the cutting of roof strips for flashing a chimney, care should be taken to have measurements correct, and cut to the line. A beveled wood strip is advised in the chimney valley, shown at A, Fig. 12, to give pitch and run the water in either direction, as desired. The sheets are usually cut as shown in Fig. 13 on straight lines and bent at dotted lines. When the chimney is smooth an edge can be turned on the perpendicular edge of flash and corners seamed on, forming a solid box around chimney, except at the bottom corners, which can be soldered or cemented. Counterflashing, as is readily understood, is, 1, a flash made from roof strips, extending up the chimney to hight desired; 2, a strip of metal extending from between two rows of brick in chimney, down and over the upturned edge of first flash, as in Fig. 14.

Where Portland or rock plaster is used it is unnecessary to use the second strip, but instead, a piece of felt or sized paper can be placed over the upturned flange or flash, and plastered over with the cement mentioned up the chimney a short distance and tapered to a feather edge at the top. This forms a pocket, and a thorough time test has proven it to be a durable and effective manner of flashing—neat in appearance. It fully provides against damage or leak in case the roof should settle around the chimney, as the felt B, Fig. 12, prevents the cement from adhering to the metallic flash and allows it to sink without disturbing the cement.

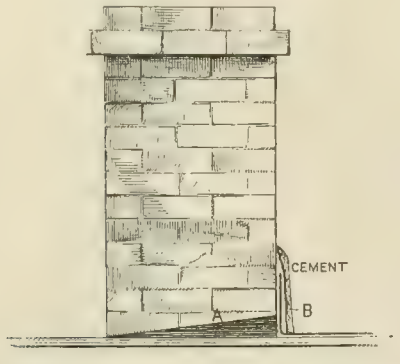


Fig. 12.—Laying Sheet in Chimney Valley.

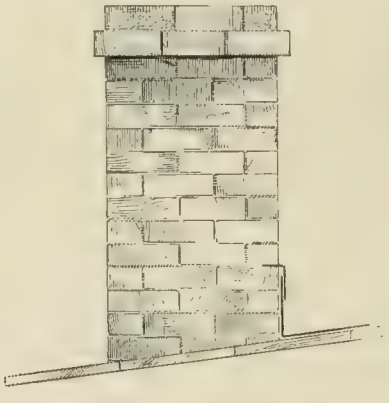

Fig. 14.—Counterflashing.

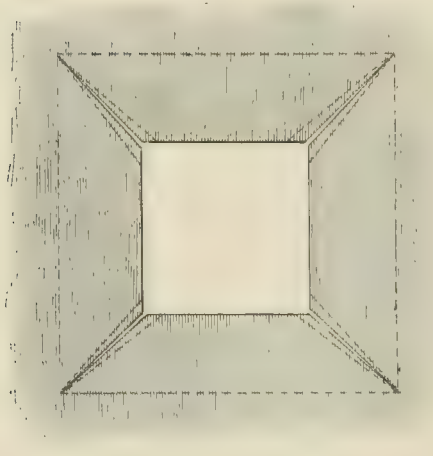

Fig. 13.—Sheets About Chimney.

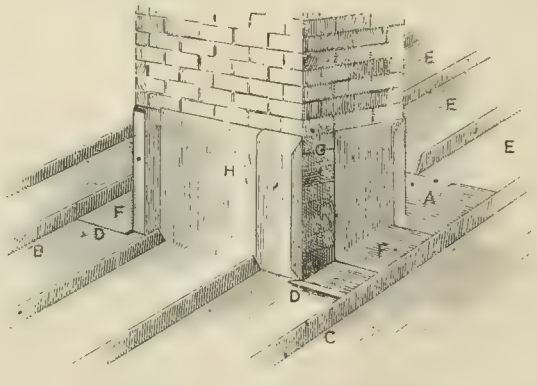

Fig. 15.—Flashing Large Chimney.

LAYING STEEL ROOFING.

When the chimney to be flashed is of such size as to require more than two sheets to pass or more than one standing seam to abut it, a valley should be laid at the upper side of the chimney, as at A, Fig. 15. For convenience the valley is usually made from steel used in roofing and laid lengthwise of the sheet. It may extend up against the back of the chimney from 4 to 6 inches, in proportion to the pitch of the roof, with the remainder of the sheet laid up the roof. A fold is turned on the upper edge of the valley sheet, and the roof strips E E E are secured to it, as shown.

The roof below the chimney is continued on from the last standing seam laid, B, on reaching the chimney until a point on the roof past the chimney has been reached, where the

* Copyrighted, 1893, by L. S. Bonbrake.

standing seam C is formed. This is done regardless of the chimney, except to turn up the flashing H and to form the folds B B to receive the folds of the side strips F F.

The strips F F are made of such width as to form the flashing for the sides of the chimney to cover the space between the standing seam and the chimney and to form the respective sides of the standing seams. They should be of such length as to allow the valley A to be seamed on at the top and extend down the roof along the side of the chimney and be hooked to the bottom roof sheets at D D. A section of the strip cut out at G, Fig. 15, exposes edges turned at D.

In Fig. 16 a view is given of the side strip, with edges turned at its top ready to receive and be attached to the valley. Fig. 17 is a perspective view of the valley sheet, with the flash H turned for the back of the chimney. The upper fold is formed to engage the roof proper and with edges turned on the right, by which it is secured on to the side strip, Fig. 16. Fig. 18 shows the valley (Fig. 17) and side (Fig. 16) connected, making the upper right-hand corner with the seams formed and ready to close. The counterflash may be made as described elsewhere.

Fig. 19 shows the manner in which a collar is seamed into the body of the roof where tile chimneys or circular stacks pass through and are to be flashed. A separate sheet is used for this purpose and the work is usually performed at the factory or shop. A band is formed of the hight wanted and fitted around the part to be flashed. An outward-turned hem is formed upon the cylinder and a hole is cut, with a flange formed in the roof sheet to fit over the cylinder and engage the hem, when it can be pinned down and double seamed, as shown. It can then be taken to the roof and edges formed to seam in and become a part of the roof. When it is not convenient to slip the collar over the cylinder to be flashed it must be made in two sections, or cut at dotted line, A A, allowing each half to be enough larger than a half circle as will provide for secure laps at each side.

When space between the stack and the collar is desired, for ventilation or other purposes, it is then necessary to counterflash over the cylinder, which may be done by forming a cone-shaped hood, Fig. 20, to fit the stack end and extend out and over the rim of the cylinder to such a distance as will provide against rain or snow blowing in through the open space. The hood can be held secure in place by means of an iron band, Fig. 21, which may encircle the flange A formed on the hood.

LAYING STEEL ROOFING.

Tinners and Roofers' Exhibits.

In the Manufactures and Liberal Arts Building at the World's Fair are a number of exhibits of interest to the tinner and the roofer.

CORTRIGHT METAL ROOFING COMPANY,

Philadelphia and Chicago, have a pretty pavilion roofed with tiles or shingles, with cresting and finials of same material. The lower part of the sides of the building is weather-boarded and the upper part covered with metal shingles, both parts painted different colors. A small portico runs across the front and the exhibit is very attractive, particularly as inside it presents a line of metal shingles as samples, and offers some easy chairs where one can rest and receive all of the information he wants from M. B. Ulleiy, who is in charge and who is a tinner of 40 years' experience.

BRYANT & WATSON,

Crawfordsville, Ind., exhibit the crestile conductor, a combined cresting, ridgeboard and electric conductor, to which finials, weather vanes or ornamental scrolls may be attached. It is to take the place of the ordinary saddle board on a roof, and being made of galvanized steel, is easily applied and durable, in addition to being more orna mental than the board in general use.

THE CANTON STEEL ROOFING COMPANY,

Canton, Ohio, show what they make that is of interest to the progressive tinner, in a pavilion made of sheet metal goods from their own plant. As a matter of course it is roofed with their specialty, the H. W. Smith patent steel roof, and painted with their anti-rust paint. The ceiling is also of sheet metal worked into an ornamental design. The upper part rests on ornamental columns and completes a very pretty structure. At the front one show board displays samples of their patent double cross lock seam roofing in plain, tinned, galvanized and painted iron, and another samples of metal shingles and stamped and corrugated iron for roofs, siding and ceiling. Inside at each end is a large ornamental ventilator, and at the back is arranged tin, copper and galvanized hanging gutter and corrugated conductor with elbows, cut-offs and hangers. Elegance is contributed to the display in the designs and the arrangement of copper and galvanized finials, crestings and cornices.

Samples of Ceylon graphite are shown from which their paint is made. Their guarantee for this paint is against cracking, peeling or absorbing moisture, and its resistance to the action of heat and acids, making it superior for smoke stacks, roofs and either wood or brick work.

FIRE AND WATER PROOF CEMENT ROOFING COMPANY,

Chicago, show a little house roofed with their cement, and samples in different colors to show the effects that may be produced. It is made of one half German Portland cement and lighter material, so that it is claimed to be 15 per cent. lighter than gravel. It can be used on steep as well as flat roofs. John G. Zallee, the patentee, can be found in the little house to give full particulars.

THE ADAMS & WESTLAKE COMPANY,

Chicago, show several tiers of large tin cans, some red, some white, some blue and some with stars, forming the flag which waves over the fair, and on the reverse side, on a blue ground, small bright tin cans form the name of the company. This flag must be 25 feet high and of appropriate length, and naturally attracts attention from quite a distance. Around it are grouped their specialties in oil cans, wire sieves, Imperial sifters and a selection of household tin goods.

KEEN & HAGERTY,

Baltimore, Md., have erected a hard wood platform and several tiers of shelves, on which they display a great variety of handsome household tinware, pieced and stamped, plain and japanned, and some handsomely decorated. This display is well calculated to fascinate the eye, and it is impossible to say what its feature is unless it be beauty, as every article is a specialty. However, a soldering copper made for a rubber hose attachment, so that it can be continually heated by gas, is surely interesting to the tinner.

IRON CLAD MFG. COMPANY,

New York, make their space look twice its size by the use of plate-glass mirrors. The space is inclosed with a nickeled railing and a skeleton pavilion is formed by using patent seamless circulating boilers for columns with small milk cans for a top ornament. From the columns nickeled bars are run to a central nickeled shaft to form the roof. From the top of the central shaft wires are run to the corners, and hung from them are letters forming the company's name. To the sides and roof thus formed are attached every article required in the household of Iron Clad enameled ware. Over 1200 little cocoa bowls in various colors are hung about, with novel and attractive effect. Their many specialties in milk cans, ash cans, ice cream cans, coal hods and soda fountains, though incongruous in use, are arranged in perfect harmony. Their new retinned stamped steel ware and the number of specialties modestly exhibited will keep many a buyer busy in assorting an order.

THE JACOB J. VOLLRATH MFG. COMPANY,

Sheboygan, Wis., lay a Brussels carpet on the floor and inclose three sides of their space with glass cases having white frames and gilt decorations, a roof with a gilt decorated ceiling arches across and supports pyramids of pans in the center and at each corner with coffee pots and tea pots along the sides. The exhibit is made up of their world's standard white enameled ware, which embraces all the known articles of use to the modern housewife. A very pretty effect is gained by a vine covered with colored leaves twining all through the exhibit. At one side, against a garnet background, the line of larger and heavier goods is shown, while on the floor are shown enameled sinks and stove reservoirs.

WAGNER MFG. COMPANY,

Sidney, Ohio, make a fine display of cast-iron hollow ware, griddles and waffle irons, ground, polished and nickel plated. A ball and socket joint is a feature of the waffle iron, so that it can be turned on a gas or gasoline stove without lifting it off and in a small space.

OHMER'S FLOUR BIN COMPANY,

Dayton, Ohio, show a novel arrangement for storing a supply of flour in a convenient place, or directly over the pastry table, which also sifts the flour and measures the quantity used. It is tastily decorated and sold at prices that seem attractive.

KINGSLEY & DAVIS,

Barrington Centre, R. I., show a nutmeg grater which, they claim, uses up the smallest pieces of the spice without the least difficulty.

C. S. OSBORNE & CO,

Newark, N. J., in addition to a fine display of leather-working tools, show their well-known gasfitters' pliers, wire-cutting nippers, screw drivers and washer cutters.

RONALDS & CO.,

Brooklyn and New York, in addition to their regular line of galvanized and copper-circulating boilers, show a novelty in various colored agate boilers marked "enameled inside and outside. Cylinders seamless. Test, 450 pounds."

D. R. SPERRY & CO.,

Batavia, Ill., make a novel exhibit by forming a pavilion of their heavy hollow-ware. The columns are formed of druggists' mortars connected at the top by cast braces supporting a series of globes formed by placing one cauldron upside down on another and these in turn support four pyramids of sugar kettles which gradually diminish in size, supporting as a top piece a mammoth globe made of cauldrons, the upper half being gilded and the lower half decorated with their trade-mark, which is Macbeth's witches around the boiling cauldron. White letters with red shading are used to enumerate the different kinds of kettles and cauldrons made by them.

SMITH & ANTHONY STOVE COMPANY,

Boston, Mass., show cauldrons from 20 up to 125 gallons, painted white with gilt letters and substantial black legs. They are furnished with copper hinged covers and openings for pipe connections when steam is to be the heating or cooking agency.

GRISWOLD MFG. COMPANY,

Erie, Pa., have three sides of their space inclosed with show cases having black frames decorated in gilt, while above them on a black background "Griswold's Erie Ware" is formed by miniature polished spiders. The front is barred by a chain of miniature nickel-plated tea kettles. The cases are filled with spiders, griddles, broilers, waffle irons, Scotch bowls, pots and tea kettles, some plain, some polished and some nickle plated. The American dampers are shown in various sizes, and though 2,000,000 were sold last year, the demand to date this year is a "tip" on its popularity and the future possibilities after it has been seen at the fair. In the center of the exhibit are waffle irons, which present every desirable feature for use, and can be turned on any stove without removing, or be removed without the parts shifting. They are made to cook several small individual waffles or as a large iron to furnish the usual four triangular temptations. Prices of the miniature goods displayed are printed, with an invitation to send for a Columbian souvenir, the card having holes for the coin and a flap to paste over it.

FLASHINGS.

THE LONG STEEL & IRON ROOFING COMPANY, Indianapolis, Ind., publish an illustrated and descriptive catalogue of the various goods of their manufacture, including roofs, sidings and ceilings of many kinds. The circular opens with notices of corrugated sheets, tables of prices and sizes, and diagrams showing the application of the material. Then comes steel roofing, crimped roofing, beaded siding and ceiling, sheet metal weather boarding, sheet steel, pressed brick, &c.

THE STEEL CEILINGS of the porches and assembly rooms of the Mines Building at the fair were made by the Caldwell & Peterson Mfg. Company of Wheeling, W. Va., as is announced on a gilt sign on the West Virginia State Building.

AMONG the recent work completed by J. Foerster & Son, 806 East Fifth street, New York, are the following: Galvanized iron cornice on two buildings in East Tenth street near Avenue B; similar work with window trimmings on buildings in East Third street; ornamental cornice balustrade and pediment on building in West Ninety-seventh street; cornice on store fronts on East Twenty first street; ornamental cornice, roofing and skylight for dwelling on East Fifty-seventh street. The firm have also put up the copper cable lightning rod on St. Patrick's Church at Elizabethport, N. J. Among the miscellaneous work that they are doing are the sheet-metal letters for attaching to wood and wire mesh, to be placed on the steamer "Aurora." The letters are 18 inches in hight and are raised 1½ inches.

Sealed proposals will be received at the office of the Supervising Architect, at Washington, D C., for the iron stairs and interior iron and copper work for the U. S Post Office, Court House, &c., at Troy, N. Y., in accordance with the drawings and specifications, copies of which maybe had from the Supervising Architect at Washington or at the office of the superintendent at Troy.

The Columbian Liberty Bell, which is to figure at the World's Fair, was successfully cast at the Meneely Bell Foundry, Troy, N. Y., on Thursday, June 22. A large number of historical relics were incorporated in the metal used for the casting. It was intended that the metal should be released from the furnace by Mrs. Cleveland by means of an electrical apparatus operated from Gray Gables, but the heavy storm prevailing at the time frustrated the arrangement.

World's Fair Exhibits.

The Jacob J. Vollrath Mfg. Company

of Sheboygan, Wis., make a fine exhibit of their Vollrath enameled ware. The company have recently engaged in the manufacture of steel and sheet iron enameled ware, but their exhibits are of as high an order of excellence as though they had been making this class of goods for years. They have built a very neat pavilion for their display, the sides of which are glass cases filled with specimens of all kinds of cooking utensils as well as covered vessels, teapots, coffee pots, &c. Many of the specimens are handsomely decorated. Different colors are shown. On the roof of the pavilion they have a variety of specimens of their blue and white and Imperial cast ware, in the manufacture of which the company built up their reputation in the trade. They also manufacture maslin kettles and pots, enameled on the inside and painted on the outside.

Belding Mfg. Company

of Belding, Mich., have done very well with the limited space they were allotted. They show all the regular styles of household refrigerators except sideboards. All sizes are in the display, from very small boxes for small families up to the largest made for large hotels and restaurants. Thirty-two of their grocery refrigerators are in use on the fair grounds in restaurants. The sample of this class shown in the exhibit is finished with plate-glass mirrors in each panel, making a very pretty finish and attracting much attention. The other goods shown are just as they come from the factory, but are so well finished that they make a fine display. In one style of their domestic refrigerators a sliding glass shelf is constructed to hold meat or butter. The object of this is to enable the shelf to be pulled out so that a piece of the contents can be cut off without permitting the interior of the refrigerator to be heated up during the process. When the shelf is pulled out, the closed back completely stops up the opening. The hardware on these refrigerators is elegantly nickel plated.

Detroit Corkscrew Company

of Detroit, Mich., exhibit a variety of corkscrews. The Columbus power corkscrew is of the type with a base to fit on the mouth of the bottle, when the cork is drawn up through the center. Greeley's cork extractor is a grooved flat wire with the end bent over to make a short catch. It is forced down the side of the cork, then twisted round to pull the cork out. The Puddefoot power corkscrew is a pocket corkscrew with a short fulcrum riveted at the joint. After the screw has been driven into the cork, the fulcrum is dropped on the top of the bottle and the cork is then easily drawn by leverage. The Davis pocket knife, wire cutter and lever corkscrew has a serviceable knife blade, and the wire cutter is also intended for use as a fulcrum to rest on the top of the bottle, making the cork easy to pull. The Davis corkscrew is the same without the knife blade.

C. E. Jennings & Co.,

79 Reade street, New York, exhibit in an upright glass case samples of their mechanics' tools. They are very attractively arranged in groups according to size, tacked on the back of the showcase. A small circular saw forms the center piece. It is inclosed in a frame of reamers and other bits, extending points outward. Gouges, draw shaves, ice shaves, chisels, screw drivers, plane bits, scratch awls, extension bits and back saws make another series in the enlargement of this circle, while on the extreme ends are butchers' cleavers and saws, hand saws, straight and bevel sided chisels, gouges, &c. The bottom of the case and a shelf above it are devoted mainly to a display of augers and auger bits. This is a special feature of the exhibit, the bits being of all styles of twist, and a great variety of sizes. In some of them the twist has been extended far beyond the usual length, to show the facility with which the firm can turn out this class of fine work. Sets of bits are displayed in cases. There are also cases of chisels, containing assorted sizes. Taken collectively this exhibit is particularly creditable and noteworthy.

Vienna Enamel & Stamping Company

of Porter, Ind., whose main office is at 149 Lake street, Chicago, have adopted an original method of attracting attention to their display. Having a corner space they have carpeted the corner and left it uninclosed, running an upright showcase along the rear sides. On shelves in the case they exhibit their enameled ware in marbled, mottled, deep blue and white finish, introducing variations from these types to show the capabilities of their process. The goods shown cover table ware, decorated drinking cups, tea and coffee pots, toilet sets and cooking utensils. The lower part of the showcase is decorated with metal panels of beautiful designs, handsomely enameled.

Universal Sad Iron Company

of Milwaukee, Wis., have a large oak showcase, with glass sides, in which they show a large number of their sad irons arranged in pyramidal form. These sad irons are self-heating, being really charcoal stoves. They are made in several sizes, for family use or for dressmakers or tailors.

Stone Mfg. Company

of Columbus, Ohio, exhibit the Stone clothes wringer. They have erected for this purpose a series of shelves in pyramidal form, made of small channel iron, supported by a frame work of bar iron and angles. The channels for the shelves are placed just far enough apart to receive the feet of the wringers. The structure is thus light in appearance and very tasteful. These wringers are made with all-metal frames, galvanized. Interspersed among them are a number of toy wringers, exact reproductions in miniature of the commercial sizes. T. W. Stone, inventor of this wringer, is in charge of the exhibit. He has just brought out a new wringer named the Progress, one of which is on exhibition. This wringer is exceedingly simple, having no bolts, screws, threads or nuts. It adjusts for any thickness by means of a horseshoe spring, the ends of which are connected with the rolls. The metal table in the front of the rolls is pivoted on the inside clamp, so that when it is raised the rolls are released and the wringer can be moved from the tub. This is an entirely new feature in a wringer, the patent having been granted without any reference to any previous patent. It will be regularly manufactured by this company.

Hurd Refrigerator Company

of Duluth, Minn., make an unusually fine display of their refrigerators. They have finished them in carefully selected woods, which have been given a piano polish, while the interiors are lined with sheet copper tinned, instead of the usual galvanized iron. A fine sideboard in curled maple, natural finish, attracts particular attention. It has a high double closet with plate-glass doors, under which is a plate-glass mirror the full width of the refrigerator. The hardware is of solid bronze in a very pretty pattern. A tank for drinking water occupies the space in the center between the two compartments of the refrigerator. Another very pretty sideboard shown is in red oak. There are also grocers' refrigerators, various styles of domestic refrigerators and narrow apartment house refrigerators.

J. S. Thompson

of Erie, Pa., exhibits two of his North Pole refrigerators. The Crystal pattern of this refrigerator is lined with glass, making a very clean receptacle for the storage of food, and also free from any odor connected with a wood lining.

Alaska Refrigerator Company

of Muskegon, Mich., have a two-story pavilion, built of oak. This is an extremely handsome piece of work and attracts much attention. The posts are beautifully carved, with carved capitals. The roof of the second story is in oak panels, while the ceiling of the first floor is mirrored in panels. A neat stairway gives access to the second story. Here is the desk of J. Chapin, in charge of the exhibit. There are also on this floor a sideboard and some domestic refrigerators, one of which is kept in use to show its system of refrigeration. Below are a number of the company's goods taken from their regular line, finished just as they go to the trade. The display comprises sideboards, grocers' and florists' refrigerators, a beer cooler and a line of domestic goods, all built on the well-known Alaska system of refrigeration.

Wisconsin Refrigerator Company

of Eau Claire, Wis., have a very good display of their Peerless refrigerators. The gem of this collection is a full mahogany sideboard refrigerator, made to order for a customer. It is beautifully carved and paneled, has a large plate-glass mirror in the top and is supplied with compartments in addition to the food and ice compartments. This stands on an elevated platform, approached by a short flight of steps laid in parquetry. The other refrigerators shown are just as taken from stock. They are well made, however, and finely finished in every detail. The point specially made in the construction of these refrigerators is to secure easy access to all the flues so that they can be readily cleaned. The sides of the flues are lined with wood, on the theory that the moisture condensing on metallic surfaces would obstruct the free passage of air.

It is stated on French authority that the Panama Canal works will be resumed at the end of the current year, and that for this purpose $10,000,000 have already been raised. The gulls are not all dead yet.

The railway and tramway lines in Teheran, Persia, and its environs, lately owned by a Belgian company, have passed into the hands of the Russians, who are extending them considerably.

STEAM AND HOT WATER.

Hight of Horizontal Steam Mains.

From J. M , *Pennsylvania.*—As there is much diversity of opinion among steam fitters in my neighborhood as to the proper hight of horizontal main at the lowest point in a gravity return above the water line in the boiler, I wish you would state what it should be for runs of 100, 200 and 400 feet; also the quickest way of finding the length of pipe in running 45° L's without using a level.

Answer.—The above inquiries were submitted to M. W. Mackay, the well-known expert in steam and hot-water heating, who furnishes us the following answer:

Regarding the proper hight at which the lowest point of a horizontal steam main should be located above the water line in a steam heating apparatus at different distances from the boiler, would say that, in my opinion, distance does not make any material difference except in long runs, where the sizes of the mains are placed too small or in such a manner as to give friction. In such cases a greater hight would be an advantage, but the proper cure would be to place larger mains, and while I have a number of good working apparatus where the distance between the lowest point of the horizontal steam main and the water line is less than 1 foot, still I have made a practice of recommending that the horizontal main, at its lowest point, should be at least 2 feet above the water line of the boiler. This might necessitate pitting the boiler in some cases, but placing the boiler on the cellar bottom without a pit, with the horizontal steam piping nearer the water line, would possibly result in flooding the steam main and cause a failure or partial failure. If fitters would make a practice of carrying the steam main at its lowest point 2 feet above the water line, and use ample area in mains they would have no trouble on the score of flooding the steam main, regardless of how long the steam main may be.

Regarding the quickest method of figuring the length of pipe required, where 45° elbows are used, I have found that the simplest and easiest way for a fitter to get the length of the pipe that he requires is to describe a square, either full size or reduced to a scale, the size of the square being equal to the distance apart that the parallel lines are required to run. Taking his measurement diagonally across this square from corner to corner and deducting the space taken up by the elbows will give him the measurement of the pipe easier and quicker than in any other way. This rule is always practical and is readily understood by the fitters.

English Practice in Hot-Water Heating—XXIV.*

EXAMPLES OF BUILDING WORKS.—(*Continued*)

The next example that may be suggested is as Fig. 97. This is an apparatus extending away from the boiler in two different directions, for the purpose of heating two rooms of different size and in different manner. Taking the boiler first, this is shown having two flow pipes off the top, and each flow has a stop valve near the boiler, as shown.

When it is convenient to have two flow pipes in this manner. it is as well to use them, although one flow which is immediately branched in two directions has no bad features; in this latter case the single pipe should be a size larger. In an apparatus such as this, especially as it does not appear to be extending far in hight, the main or general services should be 1¼ inches; 1 inch might do in some cases, but is not recommended. The returns are usually brought right back to the boiler, although there would be no objection to their being branched into one if they met at some distance from the boiler (this is not the case in the example given). If the two services terminate in a single return, it would be well to have this of a size larger pipe, as suggested with a single flow. An emptying cock and cleaning plugs must be provided to the boiler, and when placing the boiler there must be room enough in front of it for the cleaning and stoking tools to be used.

Each flow pipe should have a stop valve in it, so as to regulate the heat in either direction as occasion may require, and also to check the possible inclination one service may have to work more freely than the other. Hitherto we have suggested giving the longest service a greater rise, if possible, so as to equalize results, and this may be done in this case if convenient, but stop cocks must be provided as well. We cannot suppose that both rooms want to be heated at the same time and to the same extent always, and on this account alone the stop cocks are needed.

The service shown as proceeding to the left goes to heat a large room, requiring three radiators—a billiard room, for instance. Speaking of billiard rooms, let the reader be cautioned against putting pipes or coils under the billiard table; nothing more improper could be done. If the pipes in question are sufficient to heat the room, they will pull the table to pieces. The writer was once consulted respecting a billiard room that some one had attempted to heat by a single radiator placed under the table. Fortunately for the table, the radiator was not a large one; it failed to heat the room and did no injury; but even with this insufficient heat the players complained of the heated air ascending from under the table and coming directly to the face when in the act of resting on the board to play. No heating appliances should be under a billiard table.

* Reprinted from the *London Builder.*

The illustration is intended to show the radiators placed around the room, in corners or at most convenient points. They must not, however, be too near wainscoting or similar wood work, or the heat will injure it. The radiators are shown of different shapes, but this is settled by the general conditions. The method of connecting them, however, requires a little explanation.

The nearest radiator is shown connected by a distinct branch flow and return from the main service ; this is the best way to treat this one. The next, in the left-hand corner, is connected to the flow only as shown and as described in Article XXII. The last radiator on the right has the main flow and return directly connected with it; it really forms a terminal to these pipes, as illustrated. Each of these radiators would need the usual air cock on the top. There would be no need for a stop valve to each, as although one may heat quicker than the other, the whole three would soon become of an even temperature. The mains with this apparatus should be 1¼ inch, but the pipes or branches from the mains into the radiators need only be 1 inch, or ¾ inch will do sometimes.

The service to the right may be supposed to furnish heat to a smaller room, but one of such a character that radiators, however good in appearance, would be objectionable. In this case the radiating media must be put out of sight, and this example shows it placed beneath the floor. In a new building arrangements can be made for pipes to be carried whichever way may be most suitable; but such works as these are more often put in residences already occupied, but which have certain rooms that should have a regular heat, or which the ordinary fire places are not successful in heating. This latter trouble often occurs. There are numbers of rooms, even as large or larger than billiard rooms, that have only one fire place, which cannot heat the whole of the room, although it may be large enough to cause an intolerable heat at the end where it is situated.

The writer's usual plan when the heating pipes have to be beneath a floor is first to see that the room below is an unimportant one—a kitchen or servants' offices; then to cut away the plaster of the ceiling and secure an ordinary pipe coil with box ends up to the joists. Immediately above the coil, on the top side of the joists, a suitable sized hole is cut in the floor boards and a brass grating laid in. The pattern of the grating should be open, yet strong enough to bear being stood upon. Branch flow and return pipes enter the box ends of the coil as shown, but with coils lying flat it is best to let the flow pipe enter at a point as far removed from the return as possible, so as to insure the passage of hot water through all the pipes. (It is not as if the coils stood upright, when it is recommended to connect all pipes at the bottom only, as the heated water then readily finds its way through the top pipes without any special provision.)

Thus far the arrangement is sufficient to heat the room, as although the coils are on the ceiling of the room below, all the heat would come up through the joists and gratings, but there are two things further to consider. First, the coils would have an exceedingly bad appearance below, and secondly, and most important, all

the impure air and possible odors (if a kitchen) will come through with the most undesirable speed imaginable. The coils must be boxed in below; this will totally hide them and will make the ceiling sound, and, when whitened, of ordinary appearance except for the square box projections that must exist. To do away with those boxes the joists would have to be cut through and trimmed to make a space for the coil; this would be a somewhat expensive and troublesome undertaking. Notwithstanding the box below, which quite shuts off communication between the room above and below, the spaces between the joists should be soundly stopped also, or air may be drawn this way from disagreeable sources. When this is done the coil will heat theair of the room only; it will be practically a coil in a box, or well, sunk in the floor, but, if convenient or desirable, a fresh-air conduit could be led to it from outside. There would then be a rapid inflow of air, warmed by contact with the coil, and an inlet of this kind always goes to reduce the disagreeable drafts at doors and windows.

Air cocks would have to be put on the highest points of the coils, and when requiring attention could be got at by removing the gratings. If this is inconvenient, small tubes can be carried from the same points, but either up or down, whichever is best, and terminating with cocks.

With an apparatus like this an expansion pipe should be provided; ¾-inch would do, and the proper point for it to start from would be in the flow pipe somewhere between the two stop cocks. The cold supply would be provided for by a good-sized cistern fixed at any point from 1 foot to 4 feet above the top of the highest radiator, Fig. 98. The supply pipe might be led into any of the return pipes with the necessary dip or syphon.

Doubtless many of our readers have heard that it is proper in some instances to connect all radiating pipes, coils, &c., to the main return service only. This is correct in some cases, but in none of the examples yet given is it necessary or desirable. The methods shown are as good as any. The idea of putting all radiating media on the main return arises from the argument that the service pipe which has the greatest weight of water in it or connected with it should be the one that has the water descending within it when at work. In other words, if the flow pipe had a greater bulk of water in connection with it than the return it would tend to be an obstacle to the upward direction of the water when it goes to rise up this pipe, and having a greater amount of water to displace than there is in the return pipe it might bring about a reversed or retrograde circulation.

This theory is broken down a great deal now, yet, at the same time, when an apparatus extends in a vertical direction a good hight, and the engineer has any fear of such a result, he may put his coils all on the return, as Fig. 98, for instance. This shows an apparatus with a boiler in the basement, but going to heat two corridors or rooms a floor or two above. If it was feared the upper coils, or pipes, would give better results than the lower, then the circulation to each could be equalized by running the services as in Fig. 99. If it is not desired to make the connections wholly with the return pipe, then it could be carried out as in Fig. 100, which is, perhaps, the most customary way of doing it now.

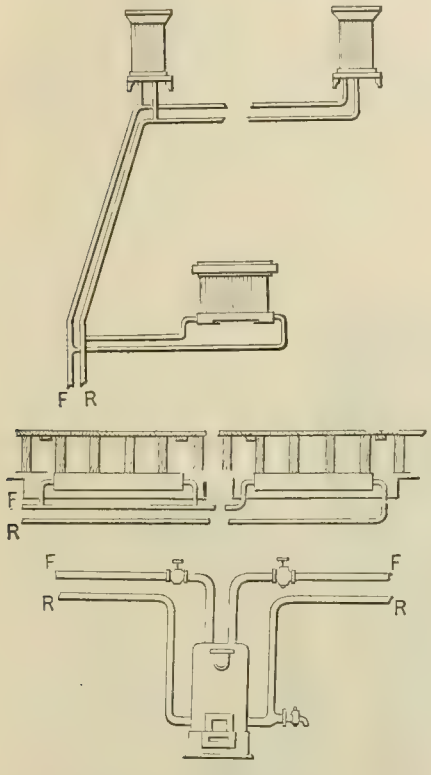

Fig. 97.—Showing Boiler and Connections for Heating Two Rooms of Different Size and in a Different Manner.

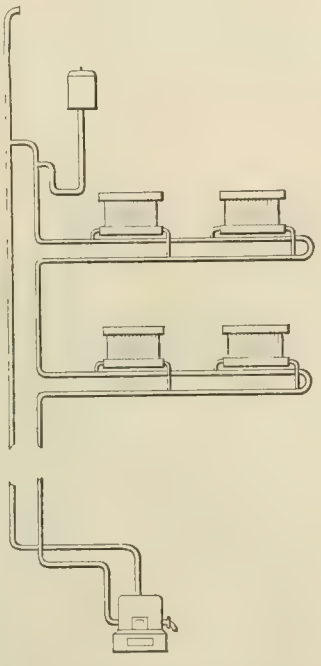

Fig. 98 —Another Arrangement which may be Employed.

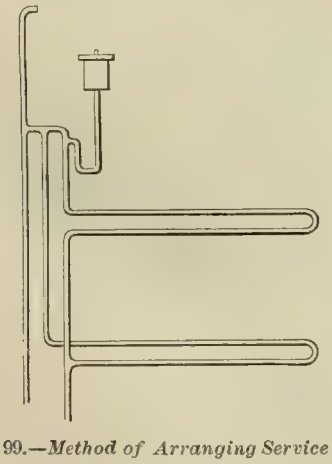

Fig. 99.—Method of Arranging Service Pipes to Secure Equalization of Circulation.

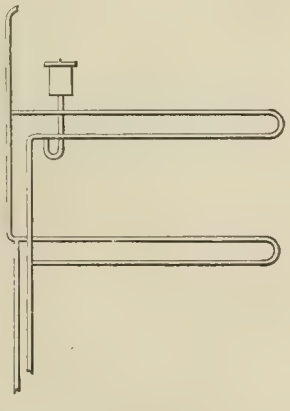

Fig. 100.—Customary Method of Arranging Service Pipes.

ENGLISH PRACTICE IN HOT-WATER HEATING.

HEATING NOTES.

The Richmond Stove Company, Norwich, Conn., have gotten up blank forms that have more than the usual interest for the steam and hot-water heating trade. One of the forms is an estimate of cost, &c., for heating apparatus. On the outside lines are left for all the particulars of owner, date, contractor, location, &c. Within, the blank is suitably ruled for making a complete estimate of cost, one-half being memoranda for radiation and the other memoranda of cost. All the items that enter into a job of this kind are provided for, and space is left for memoranda of sundry estimates. The blank will be found most convenient for those who are estimating on steam and hot-water heating work. A second form issued by the same company is a specification and contract, leaving blanks for the insertion of the amounts, &c., relating to the particular job in hand. A similar form of contract is prepared for steam heating.

The B. F. Sturtevant Company, Boston, Mass., have printed a third edition of 10,000 copies of their 200-page General Catalogue No. 61, which describes the uses of their blowers, exhausters, engines, forges and heating and ventilating apparatus.

The Raymond & Campbell Mfg. Company, Middletown, Pa., distribute an attractive little circular, printed in red and black ink, respecting the Lindemuth Sun steam and hot-water heaters of their manufacture. In the pages are given full particulars of this apparatus, and numerous illustrations show all its features of construction. A price-list and table of sizes accompany the text.

The excellence of our fruit carrying service by rail excites the admiration of foreign visitors to the United States.

The Pittsburgh Gas Engine.

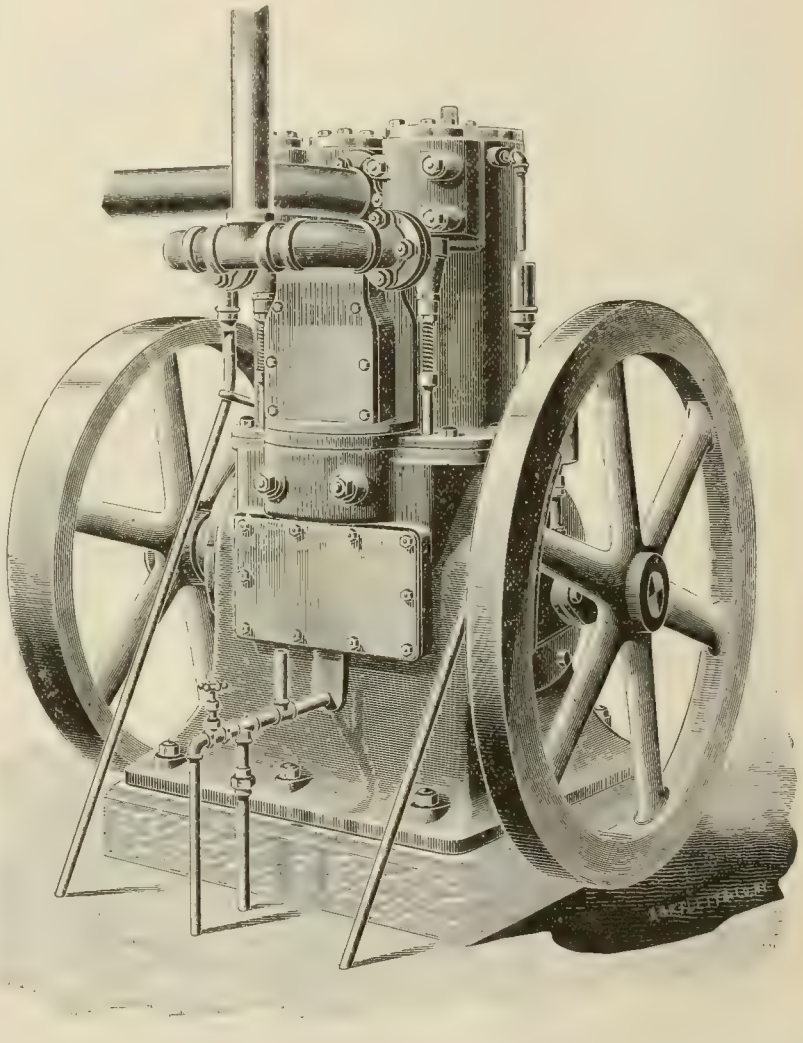
In designing the Pittsburgh gas engine the aim of Albert Schmid, superintendent of the Westinghouse Electric & Mfg. Company, and of Mr. Bechfeld, was to produce an engine possessing the following characteristics: Close regulation under the widest variations of load; an admission device that would admit gas in quantities exactly proportioned to the power required; an ignition device that would be absolutely positive and efficient in its action; to provide complete jacketing and thorough lubrication; and to be compact and simple in its general design and to have all parts easily accessible.

The engine here illustrated is made by the Fuel Gas & Mfg. Company of Pittsburgh, Pa., in sizes from ¼ up to 200 brake horse-power. As the principles of design and operation are the same for all these engines, a brief description of a single example will embody the characteristics of the whole class. The most striking innovation is found in the use of a crank chamber to inclose the bearings and lower end of the cylinders. This chamber is filled almost up to the shaft with a mixture of oil and water, into which the crank shaft and connecting rods splash at every revolution, so as to completely deluge the bearings, piston and interior of the cylinders, thereby not only affording copious self-lubrication, but also supplying an efficient jacket to the piston. Oil for the crank chamber is introduced through the main bearings, which are supplied from the only two oil cups on the entire engine. A simple pipe connection with a city main supplies the necessary water. Another pipe, serving to carry off the overflow, is made, by means of a funnel head, to indicate the level of the lubricants in the crank chamber.

All the Pittsburgh gas engines are built with two cylinders on a single shaft, and, as usual, abnormal heating is obviated by the employment of water jackets. Each revolution made by the engine operates valves admitting the gaseous fuel alternately to the one or the other cylinder. As the period of admission is controlled by a positive action, the crank shaft receives an impulse once each revolution, no matter what the load, but the energy of that impulse is predetermined by an independent piston valve. In order that the maximum amount of energy may be developed by the explosion of the gaseous fuel, there is but one value that the relative amount of gas and air can bear to each other. This value has been determined by a prolonged series of chemical analyses, and the company now design their measuring piston valve so that it shall always admit gas and air in their correct proportion for producing the correct maximum result, but at the same time vary the total amount of mixture directly as the work of the individual piston stroke.

The governor regulates the speed and controls the admission of gas to the cylinders. It is mounted upon the shaft, between the cranks, and, by direct connection between the eccentric rod and valve stem, insures an accurate and positive travel to the measuring slide valve.

The igniter employed is of the electric spark type. It consists, in brief, of an arm operated by a cam. At just the proper moment the arm is made to break an electric circuit, and the arc thus formed—intensified by the use of an induction coil—ignites the fuel instantly. As the arm is actuated by a positive motion, there can be no failure to produce a spark and no failure in the resulting ignition of the fuel. In order that the engine may be entirely self contained, the electric current is supplied from a galvanic cell. If preferred, however, the requisite energy may be taken from a dynamo circuit.



THE PITTSBURGH GAS ENGINE.

The Bessemer Medal.

At a meeting of the Council of the American Society of Mechanical Engineers, held June 22, the following resolution was passed on the presentation to John Fritz of the Bessemer medal by the Iron and Steel Institute of Great Britain:

It having come to the knowledge of the Council of the American Society of Mechanical Engineers that the Iron and Steel Institute of Great Britain has recently bestowed upon a member and ex-vice-president of the society the Bessemer medal for 1893, the council avail themselves of this occasion to tender their congratulations to John Fritz on the receipt of such a well-merited and distinguished honor from his friends beyond the sea.

The council desires to commend the excellent judgment of the Iron and Steel Institute in selecting for this honor one who by his genius, skill and industry through many years has done so much toward the improved metallurgical processes, and especially in the construction of the mechanical appliances now in use in the manufacture of iron and steel in this country, as to have materially aided in making this industry the important one it now is.

That in conferring the Bessemer medal in this the year of our Columbian Exposition upon an American engineer, the institute has in a pleasant way added further evidence of the kindly feelings and hearty good fellowship which in so many ways has of late marked the action of engineering societies and engineers in this country and in Europe, and we cannot but believe courtesies like this tend to a closer union of engineers in all lands; that while it is the mission of our profession to compel the rude forces and materials of nature to contribute to the welfare and comfort of mankind, it is their mission as well to bring in closer touch nations and individuals, and in this way aiding in a degree it would seem no other profession can to bring about those better days which in all ages past the world has hoped and struggled for.

The United States Commissioner of Navigation, in his report for the year ending June 30, 1892, gives the total tonnage of the Lakes fleet, including steamers and sailing vessels, canal boats and barges, as 1,183,582.55, showing an increase of 2.5 per cent. over the figures of 1891. The total number of bottoms was 3657, against 3600 in the previous year.

STOVE TRADE NOTES.

Electricity and the Stove Trade.

The subject of electricity and its possibilities as a heating medium for stoves and ranges is an interesting one, writes a well-known correspondent. While in conversation with a stove man the other day this topic was touched upon. He said he thought the day when electricity would usurp the office of the coal and wood cooking and heating stoves now in use was far distant. His first reason for this opinion was that the cost of producing the electric current was not reduced enough, and would not be for a long time to come, to make it a feasible material for the use of the common people, and it is largely the common people who use stoves. In a comparatively short time, he thought, electricity might be used extensively among the wealthy; but it is out of the question nowadays for the majority. Electricity cannot yet be furnished at a figure to begin to compete with coal; and the stove man thought that, should any competition begin in this direction, the price of coal would be reduced by the producers of fuel so that the electrical commodity would at once be too expensive in comparison with the cheaper fuel for the use of the mass of people who need heat for warmth and for cooking and other purposes.

"But," continued he, "should it happen at some future day that the electrical current could be produced in such quantities and at such a low rate that people not in independent circumstances could afford to use it, it would open up a new field for the stove manufacturer. It would not begin to destroy the stove trade, for stoves, I believe, will always be used in certain localities. If the electrical stove becomes a reality, instead of, as at present, a speculative production, the big stove manufacturers will at once turn their attention to the production of handsome bodies in which to insert the electrical heating apparatus, and to which the supply wires can be attached. This would surely give them as much of a field for manufacture as they have at present, and I believe that an immense business would be developed. It would afford much opportunity for the exercise of inventive ingenuity and would practically revolutionize the business of stove manufacturing in part, though, as I said, I do not believe that it would oust the coal and wood stove. However, a great deal of this is speculative, and until the day of the electrical stove comes no one can tell with definite prediction the probable outcome of the use of electricity as a heating medium for cooking and supplying warmth. There are many difficulties yet to be overcome and many devices to be planned and invented."

Indirectly the conversation touched upon the probability of there being a supply of stoves some day and a consequent falling off in the business of their manufacture. The stove man simply replied to this query by pointing out the fact that each year there were as many, if not more, couples getting married than the year previous, and that new couples needed new stoves. Altogether, he said the stove business was not likely to diminish for many years to come, if it did at all, and the demand for stoves and ranges bids fair to be good for a long period in the future.

The Future of the Hot-Air Furnace.

BY A. W. GLESSNER,

President of the Excelsior Steel Furnace Company, Chicago, Ill.

At the recent meeting of the Stove Manufacturers' Association, held at the Palmer House at Chicago, May 29 to 31, I am told that the status of the hot-air furnace, past, present and prospective, received careful consideration at the hands of the members present at said meeting and that the opinion was freely expressed that the days of the hot-air furnace were numbered. The reasons assigned for the early demise of my old friend, the said H. A. F., were, I am informed, chiefly that there had been no improvements made either in the construction or the installation of furnaces during the past few years and that heating by the means described continued to be very unsatisfactory, while on the other hand marked progress in steam and hot-water apparatus and installation was apparent, and these forms of heating were rapidly displacing the hot-air furnace in the better class of houses, while in the cheaper classes the furnace was about to be superseded by the improved ventiduct and double heaters made by the members of the association referred to.

These opinions, evidently carefully considered, sounded the death knell of the hot-air furnace and I was about to make preparation for the funeral when the issue of *The Metal Worker* chronicling the proceedings of the Convention of the Master Steam and Hot-Water Fitters, just held at the Revere House, Chicago, reached my desk and in reading the address of the president of the association upon the assembling of that body my eye fell upon the following commentary upon the effect on the steam and hot-water trades of the poor work done by novices in these lines during the past three years:

"Many business men have been materially injured by this method in the past three years, and the miserable success that has been met with on account of it has offered an almost unanswerable argument for furnace heating, and has caused much of the latter where hot water or steam would have been used if the faith of owners had not been entirely shattered by the miserable success their friends and neighbors had met with, which is chargeable wholly to the want of experience on the part of the man who lost money doing a wretchedly poor job.

"The sum of it all is, capital has been wasted in large quantities, contractors have been crippled; the public has been injured and imposed upon, and our line of business has received a set back that it will take a long time to recover from."

In comparing the opinions of the stove makers with the statements made by the president of the Master Steam and Hot-Water Fitters, the outsider would, naturally, give greater credence to the latter, for the reason that the former were simply discussing a theory, and a very pleasant theory at that, while the latter was stating a condition, and an exceedingly unpleasant one, to the organization of which he was the official head.

It might also be argued that the Master Steam and Hot Water Fitters, who are practical men and who come in actual competition with the hot-air contractors, would be better qualified to express an opinion on the future of the hot-air furnace than the stove makers, who occupy a plane so totally different from that of either the hot-water or hot-air contractors as to partially obscure their vision when dealing with this subject. The stove makers produce an article which, when properly made, requires for its installation a very small amount of intelligence, and practically no knowledge of the construction of the article or the scientific principles governing the construction of the same, whereas the hot-air furnace maker or boiler maker is producing an article which requires for its successful installation fully as much if not more intelligence, experience and judgment than for its successful manufacture.

In regard to the statement that there has been no improvement in furnace construction within the past few years I would say that there has been no radical departure from the older forms of furnaces, as experience has shown that these forms were effective and economical when properly installed and operated, but there have been improvements, and decided improvements, in the little things that go toward the making of the perfected apparatus, and while not apparent to the casual observer they are known and felt in the furnace trade. That there has been no improvement in the art of putting in furnaces and the science of hot-air heating I most emphatically deny. It is true that yearly there are hundreds of furnaces put in by novices which fail to give the satisfaction that was expected of them, just as there are hundreds of steam and hot-water boilers put in each year by inexperienced contractors and workmen which totally fail to do the work anticipated, but there is everywhere throughout the country a keener interest felt by the contractors of hot-air heating in the science of such heating and an earnest desire to improve in the art of locating and installing furnaces which is leading to much better work, and the general average of work done within the past two years has been very much raised, and the prospect ahead is for still better work. Much thought and study must be expended by the hot-air contractors in the planning of their work if the best results are to be obtained, and the co operation of the architect and builder must be had if great progress is to be made, as no class of labor has so much to overcome in the way of obstacles as that of the furnace contractors. But the improvement is constant and gradual and the results are apparent at the end of each year, and

these results do not point to an early death of the hot-air furnace.

(To be continued.)

Of Possible Interest to the Stove Man at the Fair.

In the Horticultural Building D. Stutzman of Ligonier, Ind., exhibits various sizes of the Stutzman improved fruit evaporator for drying all kinds of fruits. It is designed more particularly for farmers' use, a small size being made to work on the back of an ordinary cook stove. A current of warm air passes over the fruit, which is arranged in layers in a series of trays, and ample provision is made for the air that becomes charged with moisture to escape. The evaporator is made in different sizes to meet the requirements, the larger sizes being supplied with grates for heating.

Confectioners & Bakers' Supply Company of Chicago show candy furnaces, ice-cream freezers and a great variety of molds and utensils that are indispensable in the bakery and candy kitchen. The candy furnace is made in different sizes, with a series of rings on the top to give a large or small opening for different sizes of kettles.

The Hubbard Oven Company, Chicago, Ill., show one of their large size sectional portable ovens, as used in restaurant or hotel kitchens, with a pipe coil in the fire chamber for heating water in a circulating boiler. The oven has a cast-iron front with doors, and the sides are made of galvanized iron lined with non-conducting material, and the parts are fastened together with bolts. The shelves in the oven are made of slate, and a Fahrenheit pyrometer is arranged at the front so that the temperature of the oven can always be readily told. The oven stands about 5 feet high, is 6 feet long and 5 feet wide, giving a capacity for a large baking in a comparatively small space.

The Middleby Oven Company, Boston, Mass, show a bakers' oven that has the advantage of being portable and yet works in the same way as the usual brick oven. The fact that it can be moved should a baker find he has selected a poor stand or may be installed where a landlord will not go to the expense of building a brick oven is a recommendation that will be appreciated. The oven consists of a cast-iron frame work and a galvanized iron casing lined top, bottom and sides with 3 inch thick fire brick, having a 6-inch space filled with sand between the brick and the casing. A fire chamber is built in one corner with a convenient grate and ash pit underneath. An automatic damper works in connection with the door, so that when the door is opened the damper opens in a pipe which connects with the main smoke flue. This effectually prevents a blast of hot gas or steam in the face of the baker when he forgets to open the damper, and prevents the damper being left open when it should be closed. The record of sales shows an increase in demand as the oven becomes known.

New Stewart Stoves.

The Fuller-Warren Company have samples of their new Splendid Stewart base burner on exhibition in their Chicago salesrooms. The design of this stove is thoroughly new, although it is of the familiar square type. It is peculiar in the blending of the ash-pit section with the body of the stove in unusually harmonious relations with each other. There is no violent change of form, but graceful curves and rounded corners predominate equally in all parts. The sides and front of the ash-pit section are constructed with swelling panels beautifully carved. The body of the stove is circular, with numerous fret work mica doors through which every part of the fire pot can be easily reached. The top is of the deflector pattern, full nickeled. The dome is surmounted with a brass ornament of very handsome design. The interior construction is fully in keeping with the fine exterior. The grate is the Ransom combination duplex, and the fire pot is Fuller & Warren's patent sectional. The magazine cover acts automatically. Special care has been taken to secure a perfect damper system. The grate is operated from the outside. A large hot-air flue with a 6-inch opening at the bottom increases the heating power of the stove and enables it to be used as a double heater. Three sizes are made—13, 14 and 15 inch. The 14-inch is also made with a low oven. The P. P. Stewart base burner, which proved very popular last year, has been changed in some respects, improving very materially its already handsome appearance. A black frontpiece now runs down the body instead of the full nickeled piece of last year.

The Yeager-Hunter Spring City Stove Works

of Spring City, Pa., have issued from the press their annual catalogue of stoves, ranges and heaters. It is a volume of 100 pages, measuring 8¾ x 10 inches and bound in colored paper covers. The side title consists of the name and address of the company embossed in old gold script letters. The opening pages are devoted to announcements of interest to the trade, among which may be mentioned suggestions to customers on the subject of stove repairs. The leading place in the publication is given to the Model Chester, a six-hole range made in two sizes, and arranged for using horizontal or upright boiler, according to requirements. The ornamentation is very attractive and the constructive features of the latest pattern. Following this stove attention is invited to a variety of cooks and ranges made under such names as Grand Active, Queen New Era, the latter being something entirely new and having the oven door fitted with a heavy beveled French plate glass, surmounted with a nickeled name frame, bringing all parts of the oven to view when the door is closed; the Model New Era, the New Treasure, Roselle, Fireside, New Chester, Art Chester, Index, New Commercial, New Etna, Rego, Earl, Bertha and Unique. The heating stoves occupy fully one-half of the catalogue, the place of honor being given to the Active New Era, a square parlor stove made with full revertible flue. Reference is made to the system of air circulation in this stove, the ducts being so arranged as to take in the air from the back, and forming, it is claimed, a direct suction. The Active New Era has duplex and Ransom patent shaking grate combined, as well as other features of obvious utility. The Mascot and Maywood are conspicuously ornamented heaters, embodying the modern improvements. The Capital New Era, made in one size as a double heater; the Keystone, Signet, Modest New Era, Alway, Esther, Berwick, New Telephone, Espy, Positive, Sunrise, Star, Pilot and a miscellaneous assortment of globe, cannon and laundry stoves are included. Several pages are given up to a presentation of the merits of the Royal wrought-iron cylinder furnace and the Fearless steel-plate furnace. A list of hollow ware and of stoves for which fire brick can be furnished are features of the volume.

ODD PLATES.

The Richmond Stove Company, Norwich, Conn., favor us with an interesting little pamphlet entitled "The Richmond Recipes, with Hints and Helps for Mother, Daughter and Wife." The title suggests its contents, but scattered through its pages are illustrations with descriptive particulars of some of the Richmond stoves and ranges. There are also given tables of weights and measures in common use, time required for cooking summer and winter vegetables, and *menus* for plain and special dinners. At the close of the pamphlet is a table of contents and a few testimonials relating to the Richmond ranges.

The Art Stove Company of Detroit, Mich., have just completed their new engine room, which is built of brick in a substantial manner. It embodies all the modern improvements, and in it will be installed a very fine engine. We understand that this is the third time since they commenced business that the company have been compelled to increase their motive power.

The Bennett & Peck Heating and Ventilating Company, Cincinnati, Ohio, have recently put in one of their apparatus at College Hill, Ohio, also one for the Board of County Commissioners at Dayton, Ohio, while a third one has been installed at the courthouse at Brownstown, Ind.

The new plant of the Central Stove Works, Foster & Brothers, proprietors, Lebanon, Pa., is well under way, the buildings having been completed and the engine placed in position. The proprietors are daily receiving shipments of material and expect to be in readiness in all departments of the works by August. The first floor is used for office and storage purposes, the second is a finishing department, while the other floors will be employed as circumstances may require.

Anton Weiskittel, of the firm of A. Weiskittel & Son, Baltimore, Md., is the patentee of an improvement in gas stoves, and which relates to the construction of the pilot light. The stop cock is provided with a valve having a handle, while an ignitor connects with the cock in advance of the valve, so that the flow of gas to the ignitor is not affected by the adjustment of the supply valve. An important feature of the improvement is found in the fact that the movements of the ignitor are entirely independent of the supply valve of the burner, so that when the ignitor has served its purpose to light the gas at the burner, it may be adjusted out of the way of the latter, and, in fact, entirely out of the stove, if desired. It is claimed that this arrangement avoids any injury to the ignitor which might result from its continual heating by the stove burner, and it also enables the use of the pilot light to illuminate, in a measure, the room in which the stove is used.

William N. Moore, president of the Joliet Stove Works, Joliet, Ill., has patented a heating stove in the base of which are cold-air chambers extending entirely across from side to side and provided with openings for admitting and discharging cold air. Resting on

the base plate is a fire pot, supported by and secured to which is a parabola-shaped dome. An outer casing rests on and is secured to the stove base for the purpose of forming a chamber between it and the fire pot and dome and connected with the cold air chambers by means of flues.

Among the articles admitted free into Guatemala under the reciprocity treaty between the United States and that country are fire bricks, tiles of clay or glass, clay pipe, plain or barbed wire, iron railings and balconies, iron fire places or stoves, and machinery.

The Kernan Furnace Company of Utica, N. Y., are the assignees of a patent granted a short time since to William J. Owens of that place, for a hot-air furnace. The fire pot, or dome, of the furnace has a feeding section extended to the outside of the casing, within which is a draft flue which nearly encircles the fire pot and terminates at each side of the feeding section and having a series of openings into the fire pot above the fuel line. There is also a heating box within the casing below the feeding section and connected by equally contracted air passages with the ends of the encircled flue. These air passages are at right angles with the plane of the draft flue. The patentee states that the peculiar construction and arrangement of the heating box and draft flue provides for a first heating of the air in the box and a second heating in the flue. The heating box is connected with the ash-pit base by means of a flue and provided with a damper.

A. T. Nye & Son of Marietta, Ohio, are furnishing their new line of Leader oak stoves with heavy cold-rolled sheet body, lined fire pot, draw-center grate, smoke guard on the upper door, square base and nickel plated trimmings. Their new dwarf stove, known as the Opal, is offered in two sizes and is arranged for burning wood, coal or gas. It has large double front doors, half-pouch feed, single lower front swing door with iron slide, deep ash pit and two griddle holes in the top. These new goods, we understand, will be ready for the fall trade. The firm have also added a neat Leader coal cook to their assortment, and announce that five sizes are now ready. Its constructive features include oval fire box, extra wide bottom grate, large broiling and toasting surface, half swell oven doors, large bailed ash pan, cut top, Boston ring covers, draw-out hearth, and a system of oven ventilation which is claimed to be entirely satisfactory. The cook stove is referred to as being first class in all particulars, while the ornamentation is neat and effective.

The Famous Stove Company of Indianapolis, Ind., have issued a number of sheets illustrating some of their goods, to which they invite the attention of the trade. For the most part they relate to heating stoves, prominent among which may be mentioned the Magnet Oak, made with either sheet-steel or cast-iron body, heavy fire bowl and nickel trimmings. It is made in five sizes and is adapted for burning coal or wood. Under the name Magnet Franklin the company offer a very neat construction for coal or natural gas. It has round fire pot, draw-center grate and a blower made with sliding upper doors and swinging lower doors. The Home Cottage is another attractive heater made in several sizes and having two griddle holes under the swing cover. The Magnet is another member of this general class, but adapted for burning wood or gas. The Penn Franklin is made with round fire pot and sliding upper mica doors, giving the stove, it is claimed, all the advantages of both open and closed constructions.

Danville Stove & Mfg. Company, Danville, Pa, and 284 Pearl street, New York, are putting on the market two ranges, which are advances on similar goods made heretofore. The Queen Beaver is made in three sizes, viz: 8-21, 8-23 and 9-23. It has a heating attachment designed to use surplus heat for warming floors above, instead of losing it in the chimney. It is furnished with either solid or portable hearth. It has a backguard to prevent cooking or other utensils being forced off the top, and attached to this guard are two nickeled swing shelves on which dishes, &c., may be placed Reservoirs for heating water are placed at one end and can be had constructed of copper or iron. The range is supplied with or without reservoir. In the oven door at the bottom are four holes for tempering the heat of the oven by opening or closing. For purposes of embellishment a nickel band is furnished to go on the edge of the top. This range has six holes. The other range is termed the Prince Beaver. It is made in 8-18 and 9-18, with solid hearth. It has either triplex or flat grate, and is made with and without reservoir. The backguard made for the Queen Beaver will fit this or any other range made by this company. The two new pipe shelves are specially attractive and interchangeable.

The Wood Stove Foundry at West Troy, N. Y., has started up again on full time.

American gas and oil stoves, says the *Gas Engineers' Magazine* of London, are in use in Australia, France, England, Belgium, Canada, Mexico, and, to a lesser extent, in Central and South America.

No. 5 Wabash avenue, Chicago, is now the scene of a glittering display. E. A. Ireland has just unpacked and arranged for show a shipment of the latest style of urns and ornaments for stoves, and a visit will be sure to please the eye. The Western manufacturers will be well cared for by the efficient manager of the Chicago house of the Matthews & Willard Company of Waterbury, Conn.

An improvement in gasoline stoves forms the basis of a patent granted June 13 to Charles Anson Frayer of Keithsburg, Ill. The invention has, in some degree, a likeness to what is well known in steam machinery as the "sight feed," and the claim is intended to cover the novel means by which this idea is carried out in its adaptation to gasoline stoves. A hollow pendant attachment for a gasoline stove is provided with openings in its sides, and an internal glass cylinder for covering the openings. There is also provided a screw thread cap, having a screw thread opening, and located in the upper portion of the pendant, to hold the glass in place and afford a means by which to attach the pendant to a distributing pipe. The inventor refers to the advantages of this invention, especially in connection with the New Process stoves. As now made it is claimed that the fluid drops from the exits in the receiver or pendant upon a gauze and the amount of drip regulates the size of the flame. He states that under this arrangement it cannot be ascertained without removing the can just how much the drip is, or whether it is dropping at all, but by the device recently invented it is claimed that the drip can be seen at all times. Mr. Frayer has assigned the patent to himself and to George M. Clark of Chicago, Ill.

Grange Sard, vice-president of Rathbone, Sard & Co. of Albany, N. Y., has returned with his family from a trip to the Chicago Exposition. He had a very enjoyable time.

At the Fourth of July Celebration at Troy, N. Y., the stove manufacturers of that city will take a prominent part by having a number of handsome floats representing the trade. Bussey & McLeod, Fuller, Warren & Co., Phillips & Clark Stove Company, and Burdett, Smith & Co., as well as others, will make a fine showing.

The Backus heater, made at Williamsport, Pa., by the Backus Portable Steam Fireplace Heater Company, is seen in many different buildings at the World's Fair, using gas for fuel.

William S. Essick has resigned the office of president and manager of the Keystone Meter Company, and will at once engage in a brokerage business, handling principally pig iron, coal, coke, tin plates and metals. Mr. Essick is well known to the stove trade, having been actively engaged in that department of business from 1877 to 1890, and for several years was secretary of the Buckwalter Stove Company of Royersford, Pa. In his recent departure he will have occasion to renew many old acquaintances among the manufacturers and dealers, among whom he is so pleasantly and widely known.

A notice has been issued under recent date that after a long and successful career as a manufacturer of foundry facings, Robert Mackellar of Peekskill, N. Y., has retired from business. He has been succeeded by his sons Archibald and W. H. H. Mackellar, who will carry on the business under the style and title of Robert Mackellar's Sons, at 638 Central avenue, Peekskill, N. Y. Archibald Mackellar has been connected with the Peekskill facing mills for the last 25 years, and W. H. H. Mackellar has been engaged in the same line of business in the West.

The plant of the Toledo Stove Works of Toledo, Ohio, was slightly damaged by fire, which broke out in the front portion of the building on the evening of Friday, June 16. The damage, which was very slight, was fully covered by insurance.

Grinberg Brothers of 154 and 155 South street, New York, have issued an illustrated price-list, of a size convenient to carry in the pocket and consisting of 24 pages, profusely illustrated and bound in colored paper covers. The greater portion of the matter relates to Eagle gas and oil stoves as manufactured by the firm named. Attention is also given to ovens adapted for use with gas and oil stoves, and also to the Eagle elbow, stove pipe, dampers, &c.

Danville Stove & Mfg. Company, Danville, Pa., and New York office at 284 Pearl street, are offering an improved heating stove, known as the Princess Beaver, made in sizes 12, 13 and 14. Nos. 12 and 13 can be had in half-revertible flue, while all sizes are made with full revertible flues. The double heaters are furnished in sizes 13 and 14 only. While not radically different from heating stoves heretofore made by

this house, it has been remodeled so as to present an exceedingly attractive appearance. It has bulged doors and much nickel ornamentation, with the popular cabinet base nickeled, supplied with their various heating and cooking apparatus. This cabinet base permits of the stove being properly located by first placing the base in position and then lifting the stove or range into its place on the base.

The Excelsior Steel Furnace Company, 110 to 114 South Jefferson street, Chicago, have begun the issue of a little sheet called the *Excelsior Bulletin*, in which they discuss practical questions of interest to the furnace trade. The number before us treats of the cost of hot-air elbows, double safety stacks, &c.

The Peninsular Stove Company of Detroit, Mich., are distributing, with their compliments, a booklet entitled "The Child's Pictorial," which tells the story of "three little pigs." It is illustrated with numerous engravings, and, in its way, is likely to interest and amuse the little ones at home. The second and third pages of the covers are embellished with advertising matter of the Peninsular wrought steel ranges and warm air furnaces. The fourth page of the cover carries a *facsimile* of the company's trade mark, together with the name and address, and the statement that a written guarantee accompanies every Peninsular stove, range or furnace.

Chas. C. Heath & Co. of Baltimore, Md., are not adding this season to their lines of furnaces, heaters and ranges, nor have they found that they could make any improvements of importance. With the exception of one or two very slight changes their lines, therefore, will be identical with those of last season. The firm, however, in view of the success which attended their efforts last season, have made ample provision for the speedy and prompt fulfillment of all orders for their Active Domestic and Ideal furnaces and their fire-place heaters, their line of the latter including the well-known Grand Domestic, Bristol, National, Domestic Jewel, Chelsea, Linden and Crystal heaters. They are also prepared for the usual large demand for their Domestic and other ranges.

Governor Russell of Massachusetts recently discussed the World's Fair with a reporter of the Chicago *Herald* in a breezy way, referring to many things among the exhibits that he had noticed. The great stove of the Michigan Stove Company had made an impression on him, as is to be seen from his remarks on the subject, as follows: "Here, for instance, is a cook stove. You wouldn't think there was anything sensational or picturesque about a cook stove, would you? But there is, in the hands of a man entirely a Yankee. 'How shall I attract attention with my exhibit?' was the question with this particular Yankee. 'I don't know much about pavilions, and statues, and decorations, and hangings,' he probably said to himself, 'and if I go into that sort of thing I shall make a botch of it. I won't go into it. What I do know is stoves; with me the stove is the thing. By Jove, a stove it shall be!' So he builds a stove as big as a country schoolhouse, puts his other stoves within that, paints a sign on the outside of it in letters 2 feet long, illuminates the interior with electricity, and asks his friends to step in and see what he has to show. Of course it is a success. It may not be artistic, but who cares for art in the stove business? It catches the eye and rouses curiosity, and that is the main thing."

Rathbone, Sard & Co. of Albany, Chicago and Detroit, are distributing, with their compliments, a little pamphlet of pocket-size relating to Acorn stoves and ranges. The story is told in verse of Columbus discovering a new world and while yet far from land he notices a mysterious something floating in the water. With a fish net he scoops it up and finds it to be a monstrous acorn upon which is the startling inscription "Rathbone, Sard & Co., Acorn Stoves and Ranges."

John Utter, accompanied by his wife, left a short time ago for Chicago, where they expect to remain for something like two weeks. They are daily visiting the World's Fair, and in a letter to Sam they state that they are having a very enjoyable time.

Joseph Mackey, treasurer of the Fuller & Warren Company, Troy, N. Y., was in the metropolis last week visiting friends in the trade. He remained several days, and during his sojourn was the guest of J. D. & C. C. Lincoln.

"The Columbian World's Fair Souvenir Diary" is the title of a little book of a size convenient to carry in the pocket which is being distributed with the compliments of the Brand Stove Company of Milwaukee, Wis., and Chicago, Ill. The first few pages are devoted to advertising matter relative to the goods made by the company named, following which is information of interest to those visiting the World's Fair. The body of the little volume is intended to be used as a diary, there being spaces ruled for two days to a page, and the period covered being that during which the exposition is to be open. There are also several blank pages for purposes of memoranda. The book is gotten up in such a way as to prove useful to the owner, while serving to keep constantly before him a reminder of the line of goods manufactured by the Brand Stove Company.

The Union Stove Works of 70 Beekman street and 66 and 68 Gold street, New York, send us a circular of what is known as the Astor No. 25 eight-hole double oven range. It is made in portable form and for brick setting, according to requirements. The castings are highly finished and extra heavy, while the broiler opening is large, the double top removable and the ovens constructed of wrought iron. The stove is provided with dust-flue attachment, powerful water back and full low hot closets, together with sifting grate and ash pan. The manufacturers refer to this range as the handsomest of its class now before the public and as embodying the latest improvements.

The Thomas White Stove Company,

with offices and foundry at the corner of Fifth and York streets, Quincy, Ill., favor us with a copy of their thirty-first annual catalogue and price-list of stoves, ranges and hollow ware. The volume of 80 pages is bound in yellow paper covers carrying a side title, the design of which embraces a *fac-simile* of the company's trade-mark. The goods shown include a varied assortment of cook stoves, ranges and heaters, which are made in the usual styles and sizes. Special attention is invited to the Royal, a six-hole range for burning coal and offered in the usual modifications. The Home Royal for coal, the Royal Herald, a member of the same class, and the Prize Royal are among the other ranges illustrated and described. The cook stoves are offered under such names as the Modern Royal, adapted for burning coal or wood as a fuel; the Royal Garnet, the Prize Royal, the Gem City, Royal City and Forest City. In this catalogue the company show a very complete line of heaters for coal and wood, made in a variety of styles and sizes. The Royal Princess is a neat Todd stove and occupies the place of honor. It is made in one size only, and among its novel features may be mentioned openings in the bottom for removing ashes without disturbing the fire and for checking the draft. The stove also has automatic damper, which opens and closes with the door, or can be worked independently, as may be desired. The manufacturers make special note of their line of oak stoves for coal or wood, and which are made under such names as White's Oak, the Royal Oak and the Argus Oak. These embody the modern features and are referred to as being first-class in every particular. We also notice the Charm, a very neat soft coal base heater, with nickel-plated upper section, revolving fire pot, anti-clinker pull-out grate and extra damper; the Novelty, Pallas, Queen and Mary fancy parlor stoves for coal or wood; the Ocean Wave and Snow Bird box stoves, the Mary, Triumph and Novelty parlor cooks and the Jewel, Argus, Trump and Silver cannon stoves. The catalogue is neatly arranged and concludes with a list of stove hollow ware subject to special discount.

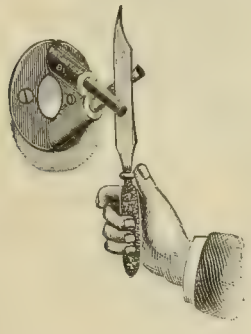
The Famous Aurora Base Burner.

The Brand Stove Company of Milwaukee and Chicago have brought out a new anthracite base burner named Famous Aurora. It is fitted with the Ransom combination duplex grate, has a large tea-kettle attachment and is supplied with a ventiduct of extra size. The flues for this purpose pass up both sides of the ash-pit walls and have no connection with the interior of the stove, thus avoiding leakage of gas. A damper is arranged so as to throw the heated air into the room or through a pipe into another room when used as a double heater. It is a three-flue stove, on the principle first used in the Square Brilliant, made by this company. The general shape of the stove is square, with rounded corners and curved outline. The body is round, tapering in at the top of the mica section. The top is square, with deflectors on three sides, graceful brackets apparently supporting the top. The swing cover is also square, with an appropriate urn of jet, bronze and nickel. The design of this stove is unique. The manufacturers desired something new and distinctive in appearance, and began at the bottom. There is a double foot rail on either side, and another in front in place of the usual hearth. No corners appear in the body section. Very large mica doors swing right and left, opening all the way to the back and overlapping a narrow front piece with a watch-case fit. Below these doors are four slotted hinge doors for inserting a poker, avoiding the constant use of the large doors for this purpose. The magazine is cast with an ornamental design. The entire stove is well proportioned, and will rank among the really handsome stoves brought out this year. Three sizes are made, 14, 15 and 16 inches.

THE RETAIL STORE.

Foster's Knife Sharpener.

John Chatillon & Sons, 85–89 Cliff street, New York, are offering the sharpener as here shown for sharpening carving or other knives. It consists of two straight pieces of steel ⅜ by 3 inches in size, roughened in the



Duplex Steel for Sharpening Knives.

same manner as butchers' steels. The pieces of steel are held rigidly at a proper angle by means of two cast-iron sections, drawn together by a screw and nut in the center. It is intended the sharpener should be screwed permanently to the wall or other convenient place. The knife is sharpened by drawing it firmly between the steels a few times. The entire surface of the steels may be used by turning and reversing them as found necessary.

Little Giant Steel Truck.

The Little Giant Truck Company, Syracuse, N. Y., are introducing the

Little Giant Steel Truck.

truck illustrated herewith. It is described as being made entirely of metal, with well-fitted bearings, with no wood in its make-up to shrink, warp or decay. The truck combines strength with lightness, the manufacturers stating that it weighs but 14 pounds and will carry 500 pounds. The adjustable clamp, operated by an eccentric lever, is referred to as a sure and positive grip on a barrel, and its range of adjustment as permitting various sizes of barrels to be handled on the same truck, while its compactness and practical indestructibility are features emphasized by the makers. The truck is recommended for light general use, such as moving flour, sugar, ash and garbage barrels, &c., and is known as No. 1. A No. 2 truck is soon to be ready for the market adapted for heavy work, such as oil, liquor barrels, boxes, &c. The trucks are finished in japan and vermilion.

Travelers' Drinking Cup.

Illustrations are herewith given of a folding cup which has been put on the market by F. H. Clifford, 265 Dearborn

Fig. 1.—Travelers' Drinking Cup.

street, Chicago. Fig. 1 shows the cup open, ready for use, and Fig. 2 represents it closed. It is made with five parts and a handle. When closed it is about ¾ inch in hight. It is described as being made with a screw in the bottom which works into a slot in the handle, so that by revolving the bottom the screw becomes tightly fastened to the handle, thus drawing the parts together, making a tight package. On

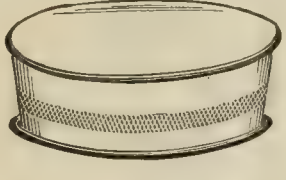


Fig. 2.—Drinking Cup Closed.

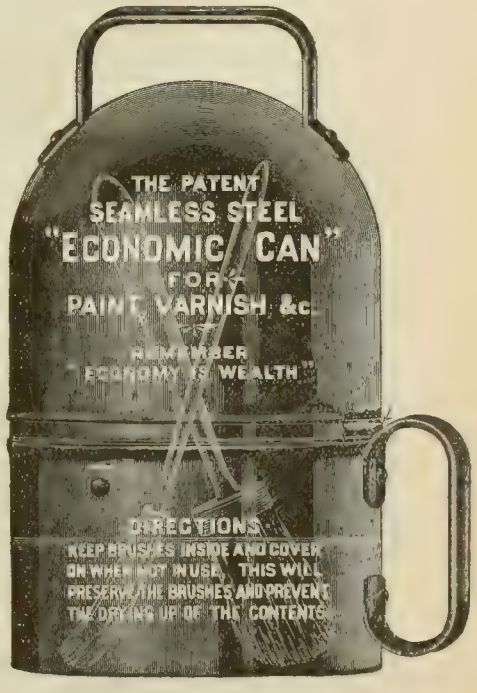
unscrewing the bottom the handle is loosened and when the rings are pulled out the handle is thrown over, as shown in Fig. 1 and braced against the rim on the bottom, being further held in place by a slight projection passing through the slot shown on the handle. The cup, it is stated, is then rigid, will not collapse in the hand and can be operated with the handle instead of putting the fingers in the top of the cup as usual. The manufacturers state that it is strongly made of white metal, nickel plated, is handsome in appearance as well as being strong.

Economic Can.

The Wilmot & Hobbs Mfg. Company, Bridgeport, Conn., and 20 Murray street, New York, are introducing the Economic can, as here shown. The can is 9 inches high and 6 inches in diameter. Both top and bottom are seamless, being formed from Swedoh steel, with no seams to leak. Where the two



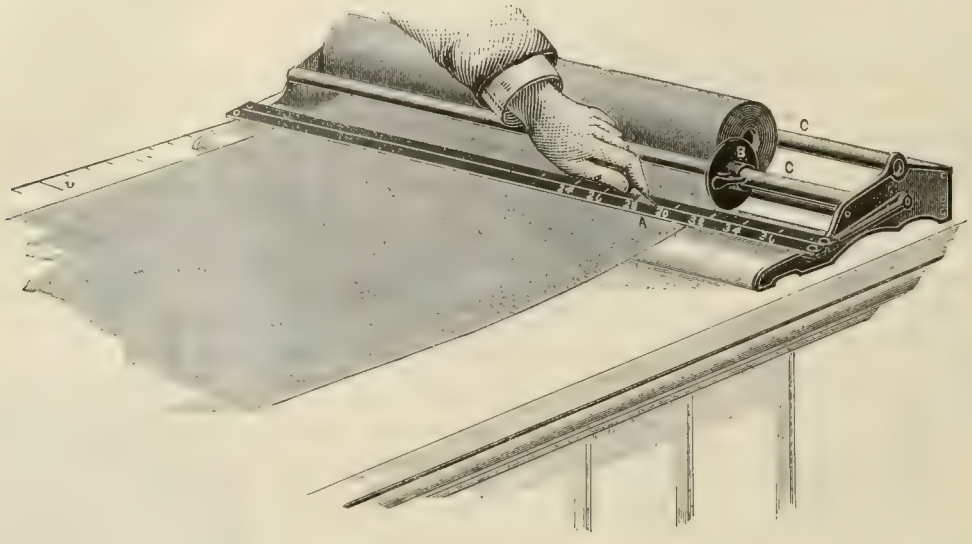
Seamless Varnish or Shellac Can.

sections are joined is a rubber cushion, making, it is stated, a tight joint and hermetically sealing the can. Two wide flat steel springs fastened by rivets, holding the handle to the dome, and projecting an inch or more below the rubber, keep the two parts together, which, the makers say, will sustain 10 pounds weight. There is a piece of metal riveted to the inside of the can, on which the brush may be wiped to relieve it of surplus material. There is also a formation of wire with two hooks that can be slipped on the metal piece alluded to to hang the brush on. The can is black japanned, and very attractive in appearance. The bottom section will hold conveniently 1 quart. The can is designed for the use of painters, pattern and cabinet makers, and all who use fine material, especially shellac and varnish. The hermetical sealing of the can when closed is intended to preserve brushes and varnish by preventing evaporation, thus avoiding the necessity of cleaning the brushes and the formation of skins.

THE HARDWARE FIRM of W. H. Crane & Son, formerly Crane & Parker of Binghamton, N. Y., have been succeeded by Crane & Lockwood. The senior member has been engaged in the business 13 years, and the firm has been a prosperous one.

I X L Combined Wire Cloth Roller, Cutter and Rewinding Machine.

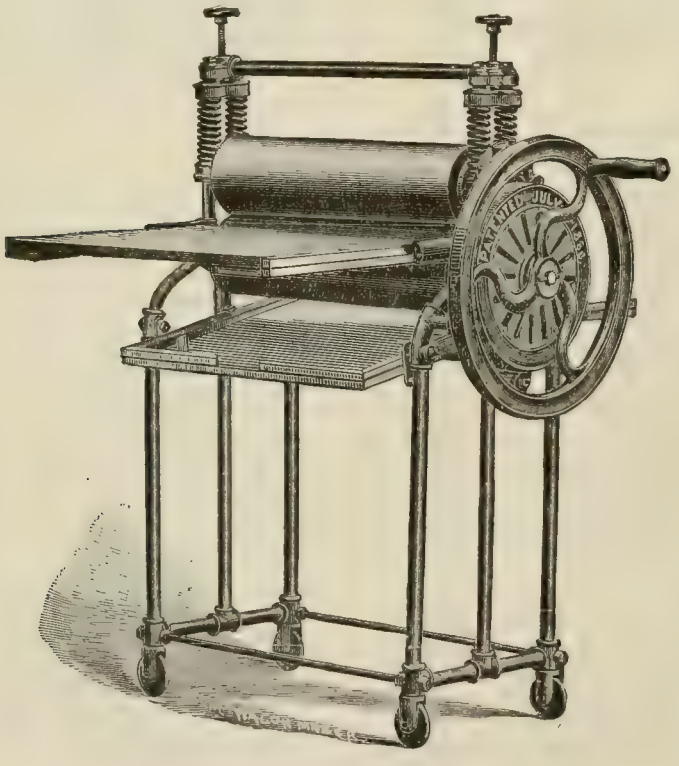
O, P. Schriver & Co., Pearl and Sycamore streets, Cincinnati, Ohio, are putting the above machine on the market, as illustrated in the accompanying cut. The machine consists of a frame in which there are three rolls, C C, which revolve when the cloth is laid on them and pulled out. The washer B is movable on the front roll, and is designed to keep the wire cloth from running sideways. The cutting bar throws back out of the way while the cloth is being pulled out on the counter the length required, ready for cutting off. The bar has a slot corresponding to a slot in the frame, in both of which the knife runs in cutting, thus insuring a straight cut. When the cloth is put in the machine the figures on the frame tell the width, thus avoiding mistakes. For rewinding wire cloth a split bar is used, fitting in holes provided for that purpose in the frame. The manufacturers state that cloth is thus rewound in as compact a form as when it comes from the factory, that 100 feet of cloth can be rewound in a minute and a half, ready to give to a customer, and that remnants as well as full rolls may be unrolled on the machine without any changing of the rolls.



I X L Combined Wire Cloth Roller, Cutter and Rewinding Machine.

The Eclipse Mangle.

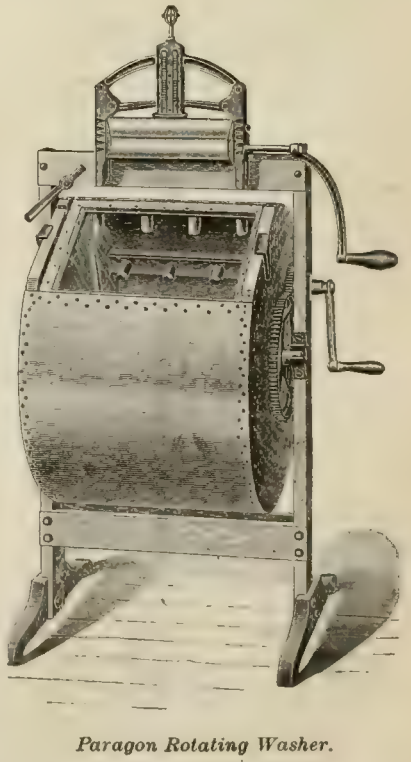
The accompanying cut represents a mangle put on the market by the Lang Mfg. Company, Racine, Wis. The machine is described as having a cast-iron frame tied by wrought-iron bars, with the parts geared to secure a pressure of 2000 pounds, having the gearing so adjusted as to make the operation of the machine easy. The rolls are of selected white maple, treated by a process to prevent shrinkage or checking. The manufacturers claim that by the use of the machine a fine gloss is obtained; that there is no possible chance of scorching the goods, and that a mangle will do the work of six expert workmen, with a child to turn it while a woman runs through the plain goods. The mangles are made in two sizes, 24 and 27 inch rollers.



The Eclipse Mangle.

Paragon Rotating Washer.

Olds Wagon Works, Fort Wayne, Ind., are introducing this washer, as herewith shown. Its operation is described as simple, combining the principles of the old pounding barrel together with the abrasion of the clothes in contact with themselves, being an effective rubbing with the least possible wear and tear. Attention is called to the symmetry and mechanical finish of the machine throughout.



Paragon Rotating Washer.

TRADE REPORT.

The Iron Market.

The week past has been merely a repetition of several preceding, and has developed no change in the Iron market worth noting. Demand has been on the decrease, and prices show increased weakness in many cases. As yet the conference committees representing the manufacturers and the Amalgamated Association have not come to an agreement, although some six or seven meetings have been held. It is not thought, however, that any serious trouble will occur, and a settlement brought about by mutual concessions is expected to be reached at an early date.

Throughout the West the demand for Finished Iron and Steel has been larger than had been expected in view of the depressing financial conditions, as many consumers thought it advisable at last to make some preparation for the anticipated curtailment of production. The increased movement has had no effect on prices, however, which still manifest a downward tendency.

Pig Iron.—In the New York market business is still dull. Curtailment of output recently relieves the selling pressure in some degree, but there is evidently still more than enough Iron to go around, and, on other than particularly favored brands prices are weak, with some business said to have been done in low-grade foundry stock at less than our inside quotations. We quote Northern brands at $14.50 @ $15 for No. 1; $13.75 @ $14.50 for No. 2, at tidewater. Southern Iron, same delivery, $13.75 @ $14 50 for No. 1; $12.50 @ $13.50 for No. 2; $12 @ $12.25 for No. 3; $12.25 @ $12.50 for No. 2 Soft, and $12.75 @ $13.25 for No. 1 Soft.

While the supply of Pig Iron in the Philadelphia market is small the demand is still smaller, so that sales are both few and unimportant, the strong point being that deliveries are freely taken, leaving the furnaces with very little material on hand, thereby enabling producers to maintain firm prices. The demand is not expected to show much improvement during the next couple of weeks, but prices will probably remain about as follows for Philadelphia and vicinity, and from 20 to 30 cents less for Southern Irons at points accessible by water:

American Scotch, No. 1X...	$16.00 @ $16.50
American Scotch, No. 2X...	15.00 @ 15.50

At Chicago contracts covering about 30,000 tons have been secured by local Pig-Iron manufacturers from agricultural-implement manufacturers to cover their requirements during the next 12 months. Southern Foundry grades are weaker than Soft Irons under greater pressure to sell. Lake Superior Charcoal has slightly receded, as makers are, at least to some extent, endeavoring to realize on the stock which they have been so long carrying. The weakness on this class of Iron is for immediate delivery and prompt cash; season contracts would hardly be placed at the prices now current. So many Charcoal furnaces are out, and will probably be for the remainder of the year, that those who are able to carry their stocks expect to realize much better prices next fall or winter. We revise our quotations in the light of recent events, but they are subject to concessions in nearly every case for immediately delivery and for prompt cash.

Lake Superior Charcoal.....	$15.75 @ $16.00
Local Coke Foundry, No. 1...	13.50 @ 14.00
Local Coke Foundry, No. 2...	13.00 @ 13.25
Local Coke Foundry, No. 3...	12.75 @ 13.00

In Southern markets there is no improvement in the Pig-Iron trade, and the existing monetary depression seems to bear with greater weight upon the business with each succeeding week. Consumers of Pig Iron who are undoubtedly solvent cannot pay their paper as it becomes due, and must be accommodated by renewing it. There is much talk of the suspension of production of Pig Iron until more favorable times, but this matter is uncertain. While the melting of Iron is much restricted in this district, there is yet a considerable volume of business, but the purchases are mainly in single carloads. Quotations are as follows:

Foundry.

Southern Coke, No. 1.	$13.00 @ $13.25
Southern Coke, No. 2.....	11.50 @ 11.75
Southern Coke, No. 3.....	11.00 @ 11.25
Ohio Soft Stone Coal, No. 1....	16.00 @ 16.25
Ohio Soft Stone Coal, No. 2....	15.00 @ 15.25
Lake Superior Coke No. 1.....	15.00 @ 15.25
Lake Superior Coke No. 2.....	14.00 @ 14.25
Hanging Rock Charcoal, No. 1..	18.50 @ 19.00
Hanging Rock Charcoal, No. 2..	17.50 @ 18.00
Tennessee and Alabama Charcoal, No. 1.....	15.00 @ 15.50
Tennessee and Alabama Charcoal, No. 2.....	14.00 @ 14.50

Metal Market.

Pig Tin.—The sharp decline in price of Silver, along with financial complications, has caused depression in the market, under the weight of which values dropped about ½¢ @ ⅝¢ ₱ lb from the closing quotations at the date of last week's review. Business has been done during the week at as low as 19 45¢ for spot and July delivery, and sales were difficult to make at that price at the close.

Copper.—Business has been on a very moderate scale and the popular quotation for Lake Superior Ingot is 10¾¢, but some sales have been made at less, and there were faint signs that bids of 10½¢, prompt cash, would have found takers in some quarters. Electrolytic sold at 10¼¢ @ 10½¢, according to brand and size of lot. On Casting Copper there has been a decline to 9¾¢ @ 10¢, but the inside price seems to be exceptionally low at the moment.

Pig Lead—Under the pressure of liberal offering of stock for delivery during the next 60 days, prices have undergone a further decline and the market is at present suffering in no uncertain way from the weight of financial stringency. The official bullion price dropped to 3.40¢, the lowest point that has been touched in a long time.

Spelter.—Dullness is still the prominent feature in the market for this metal. Prices are rather weak, with the range of 4.15¢ @ 4.25¢ quoted for Prime Western delivered here.

Antimony.—The market has been very slow, but prices are held at about 9⅞¢ for Hallett's, 10⅛¢ @ 10¼¢ for L X, and 10½¢ for Cookson's.

Tin Plate.—There is no change in the condition of the market; certainly none for the better as far as sales or demand are concerned. Aside from occasional lots of special sizes the purchases for future delivery are still extremely slim and spot goods are taken in very moderate quantities. Prices are rather weak all along the line but show no radical change.

Chicago Report.

Scrap.—There is so little demand from consumers for anything except Cast Scrap that dealers hesitate to make offers. They would probably buy at about the following rates:

	Per net ton.	Per lb
No. 1 Wrought Scrap.....	$10.00	....
Machinery Cast.....	7.50	....
Malleable Cast.....	7.00	....
Stove Plate (free of burnt)..	5.00	....
Burnt Iron and Grate Bars..	4.00	....
Sheet Iron and Hoops.. .	3.00	....
Plow Steel and Breaking Stock.....	6 00	....
No. 2, such as Shovels, Hoes, &c.....	4.50	....
Old Boilers—whole (Iron)....	6.00	....
" (Iron)—cut in single Sheets and Rings..	9.00	....
Old Gas-Pipe and Boiler Tubes.....	6 00	....
Cast Borings.....	3 50	....
Turnings.....	5.00	....
Horseshoes.....	10 00	....
Copper Bottoms.....	....	7 ¢
Copper Clips and Heavy.....	. ..	8½¢
Heavy Brass.....	....	7½¢
Light Brass.....	....	4 ¢

Pipe Lead	8 ¢
Tea Lead	21½¢
Zinc	2¾¢
Rubber	2¾¢

Anthracite.—The summer buying has not yet begun. Dealers quote carload lots of 12 net tons as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
Lincoln, Neb	9.20	9.45

CONDITION OF THE

Hardware Trade.

WITH THE CLOSE of the half year there is naturally a diminished volume of business, and, taken all in all, trade is quiet, orders being limited for the most part to small assortments of goods which are needed for early requirements. Many manufacturers are preparing for the dullness which generally prevails in July and are giving their attention to repairs and the finishing up of the six months' business. The financial situation has a good deal of influence with the larger buyers, and there is a marked indisposition on their part to make any large purchases, preferring to await developments rather than take advantage of the low prices which are prevailing in many lines. The stringency in the money market is being felt by wholesale houses and manufacturers, and it is observed that some strong concerns are not availing themselves of the usual cash discounts. At the present time more attention is being given to the scrutinizing of credits and the collection of accounts than to efforts for the sale of goods. In the matter of prices there is very little to report, the market continuing weak and in an unsatisfactory condition, but manufacturers are refraining from pushing goods upon their customers, thus preventing any material shrinkage in quotations. The volume of business during the half year has probably been nearly, if not quite, up to the average, the quiet which has prevailed during the past month or two being counterbalanced by the excellent trade with which the year opened. The indications are that July will be a quiet month, but it is hoped that with the removal of financial uncertainty and disquietude there will be a satisfactory resumption of business in good volume before long.

Advices from Chicago.—Trade in Shelf Hardware is somewhat lighter now, as summer is here, and the demand for seasonable goods is about over, except for pick-up orders to supply the scattering trade. Vacations are beginning and salesmen are taking advantage of the approaching summer dullness to visit the World's Fair. The demand for Builders' Hardware continues light, as was reported last week. Staple goods are comparatively quiet also. The trade in Heavy Hardware is very moderate for the time of the year, although some houses report a fair condition of business, greater in volume than they had reason to expect from existing conditions.

Notes on Prices.

Cut Nails.—There is only a moderate demand for Cut Nails, and prices are somewhat irregular. The quotation of $1.05 for carload lots at mill represents the market in a general way, being shaded on desirable orders. Small lots from store in New York are held at $1.30 to $1.35.

Advices from Chicago.—Manufacturers of Cut Steel Nails report an absence of large orders, but a steady influx of small orders, which keeps them moderately busy. There are no special developments in this line, but prices are held at $1.20 to $1.25, Chicago, on factory lots, and $1.30 on small lots from stock.

Wire Nails.—There has been no important change in the Wire Nail market. The mills are preparing for the shutdown in July, which will be quite general, and in anticipation of this some of the trade are sending in orders covering their requirements for that month. The aggregate of this business is not referred to as especially large, a good many of the trade having sufficient stocks on hand. The quotation of $1.35 for carload lots at mill still prevails and is maintained with a good deal of regularity, manufacturers refraining from making important concessions. The feasibility of reaching an understanding in regard to prices and production is still under consideration by the manufacturers and it is thought that the present condition of things is favorable for the success of the project. There are, however, serious difficulties in the way and what the outcome will be is uncertain.

Advices from Chicago.—The Wire-Nail trade is in a little better condition from the manufacturers' standpoint. Less pressure to sell is observable, and although prices have not been sustained at the figures named last week by sanguine sellers, a firm bottom appears to have been reached, and there is now a chance for a better condition of trade after the general shut down takes place the coming month. Quotations on factory range according to the mill, from $1.40 to $1.50, Chicago. Jobbers quote $1.60 as their regular price from stock, with concessions to best buyers.

Barb Wire.—The Barb-Wire market continues sluggish, with the moderate volume of trade prices continue unchanged at $2.45 to $2.50 for Four-Point Galvanized in carload lots at mill.

Advices from Chicago.—Orders are still coming in reasonably well for fair quantities from factory. World's Fair visitors are buying, also, to some extent. Local manufacturers have thus been favored recently with considerable Southwestern trade. Taking the whole volume of business, however, it is lighter than it was and seems to be tapering down to the usual midsummer dullness. Carload lots are quoted at $2.15 for Painted and $2.55 for Galvanized. Small lots are selling at $2.30 and $2.70, respectively.

Tackle Blocks.—The Tackle Block market continues in the demoralized condition which has prevailed for some time. It is conceded by manufacturers that the goods are selling below the cost of production, but the competition has been and continues very animated. The volume of business has been fair, but at present it is referred to as having fallen off considerably. The trade will realize how unsatisfactory the present condition is to the manufacturers when it is remembered that before the combination broke up prices were represented by a discount of 50 and 10 and 10 per cent., but that recently sales have been effected in some extreme cases at prices as low as discount 85 per cent., which represents a shrinkage in price to 15 cents as compared with 40 cents. This condition of things had doubtless something to do with the embarrassment of the Boston & Lockport Block Company, the effect of which on the market remains to be seen. It is thought not unlikely that it may have a tendency to diminish somewhat the prevailing competition and induce manufacturers to pursue a more conservative course.

Glass.—This is a season of the year when little is being done in the way of distributing Glass from factories. It is too late for jobbers to place large orders, and too early to make contracts for fall delivery. The disposition is to purchase enough only to cover immediate wants, this policy being largely enforced by the scarcity of money. Most of the factories have shut down for the summer, and, it is understood, with comparatively small stocks of Glass on hand. The National Window Glass Company have succeeded in maintaining prices, apparently under the most adverse circumstances, as in all probability the backward spring and, later, the financial uncertainty would have demoralized prices completely, if the manufacturers and jobbers had not been held in check. As it is, the outlook for good prices and better trade in the fall is encouraging. Small dealers are replenishing their stocks from jobbers, day by day, so that the Glass

handled in small quantities amounts to quite an aggregate. There are no encouraging features in the Plate-Glass market, demand continuing limited. Jobbers do not appear to be overstocked, as a rule, but the factories have as much Glass as they can conveniently carry. Quoted prices remain unchanged, as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, ton lots,	₩ lb.	@	$0.03½
Rubber Shoes, ton lots	₩ lb.	@	.04
Large Hose,	₩ ton	@	9.00
Wringer Rolls,	₩ lb	@	.04½

In an article on "Southern Progress and Prospects," J. S. Jeans, secretary of the British Iron Trade Association, says it will not excite any great surprise if in the not far distant future coal from the Southern States should be shipped to ports now supplied by England, and even to England herself.

Trade Notes.

THOS. DEVLIN & Co. of Philadelphia have just completed a handsome addition to their establishment. The new building is six stories high, 140 feet long by 40 feet wide, and will considerably increase their facilities for turning out goods, and enable them to keep well up with the increase in their trade connections.

ESTATE OF S. WHITNUM, Brooklyn, galvanizers (Edward Little, manager), have recently added a one-story extension to their works, which now cover a plot 150 feet on Driggs avenue and 200 feet on North Eleventh street. They are now engaged in galvanizing a large order recently received from the Third Avenue Railroad Company. Castings weighing over 40 tons have been received to be galvanized. Among them are the caps for the immense chimney connected with the power house. They are also engaged on a large order for galvanizing 24,000 kitchen sinks, to be finished within 60 days. A number of men have been recently added to their force, making 125 men in all. Mr. Little, the manager, is a well-known business man, and is the patentee of many well-known articles, among them being a corrugated leader and a stand for kitchen boilers.

JOHN B. HARKER & Co., 19 Fifth street, South, Minneapolis, Minn., state that the suit instituted against them 16 months since for the infringement of a patent on a Waffle Iron has been decided in their favor. The decision was a most decided refutation of the claim made against them, and they are now free to push the manufacture and sale of the Harker Waffle Iron.

Enlargement of Cramp's Shipyard.

Mayor Stuart of Philadelphia has signed an ordinance by which the long-desired facilities are given for extending Cramp's shipyard, so as to accommodate the large amount of work now on the books of that establishment. The Cramp Company will, it is said, now proceed with the construction of five great slips, over 600 feet long and 70 feet wide, which will be required for the five large American liners under contract. When all the enlargements and improvements which have been decided upon are carried into effect, Philadelphia will possess a shipbuilding plant the peer of any in the world, giving employment to a larger number of skilled mechanics and workingmen than any single industrial establishment in the Quaker City. At present there are 4500 men on the pay rolls, but 6000 will be required to run the plant on the increased scale contemplated. Cramps have now in hand seven war vessels for the Government—namely, the armored cruiser "New York," now nearing completion; the commerce destroyers "Minneapolis" and "Columbia;" battle ships "Indiana," "Massachusetts" and "Iowa," and the armored cruiser "Brooklyn." Besides these, work will shortly be commenced on the five ocean greyhounds to be built for the American line—namely, two of 10,500 tons and 540 feet long, and three of 13,000 tons, 600 feet in length. All other departments of the establishment are reported as very actively employed, the gun shops being filled with orders for the next nine months, and the brass foundry for another year.

Price-Lists, Circulars, &c.

A. I. ROOT, Medina, Ohio: Bees and Honey. This, the seventy-eighth edition of illustrated catalogue and price-list, shows, with descriptions, Implements for bee culture in large variety; also a line of miscellaneous articles.

A. B. KOCH COMPANY, Peoria, Ill.: Circulars descriptive of the Koch Patent Shiftable Reversible Shelf Brackets. These circulars illustrate the methods in which these Brackets can be used in putting up shelving. They are so contrived that the Brackets can easily be shifted to suit goods of different hights. The shelves can readily be removed from one store to another, not being "fixtures" in the ordinary sense.

OSSAWAN MILLS COMPANY, Norwich, Conn.: Twisted, Braided and Woven Goods, in silk, worsted, cotton and wire. Their illustrated catalogue, which is the first showing a complete line of their Cords, Wires and other manufactured goods, states that with machinery the manufacturers are able to make a great variety of Twisted, Braided and Woven Goods on special orders. In addition to the above-named articles, cuts are given of Picture Hooks, Screw Eyes, Screw Hooks, &c.

BOSTON EMERY WHEEL COMPANY, Waltham and Boston, Mass.: Emery and Corundum Wheels from North Carolina, Georgia and Chester Corundum; also Emery Wheel Machinery, Polishing Lathes, Strapping Machines and Automatic Knife Grinders. Special mention is made of the Ferro-Silicon and of the Boston Flexible Wheels.

WATERBURY MFG. COMPANY, Waterbury, Conn.: Brass and Nickel Harness Trimmings. The catalogue illustrates, with prices, Glass and Metal Rosettes, Spots, Nails, Terrets, Hooks and other miscellaneous Trimmings for the Harness and Saddlery trade. The book is handsomely printed on fine-quality paper, bound in flexible leather covers.

THE KILBOURNE & JACOBS MFG. COMPANY, Columbus, Ohio: Trucks. The catalogue devoted to this line of goods illustrates and describes, with prices, Baggage Barrows and Express Wagons, Store, Warehouse, Railroad, Hotel, Dry Goods, Carpet, Barrel and Wagon Trucks, Grain or Meat Wagons, Hand Carts, Skids, Push Cars, &c.

DETROIT STAMP COMPANY, Detroit, Mich.: Rubber Stamps. Their catalogue of 96 pages illustrates Stencils, Seals, Steel Stamps, Burning Brands, Checks, Badges, Type and Office Specialties, &c.

KEEN BROS. HARDWARE COMPANY, Chicago, Ill.: Mechanics' Tools. Illustrations are given of Carving Tools, Chisels, Spokeshaves, Drawing Knives, Hatchets, Planes, Rules, Levels, Screw Drivers, Hammers, Saws, Braces, Dividers, Pincers, Pliers, Plasterers' and Paper-Hangers' Tools, &c.

A good average harvest is in prospect in Canada, especially in the northwestern districts. The hay and clover crops being especially bountiful, agriculturists will have plenty of such produce to supply the demand from Great Britain which will ensue on the total failure of the grass crop in that country.

It Is Reported—

That Murer & Case's Hardware store, Norfolk, Neb., was burglarized recently, the articles taken being valued at $200.

That W. D. Ball, who has been closely identified with the business interests of Ludlow, Vt., for the past 25 years, has disposed of his Hardware store to Frank Howard of Springfield, Mass., and Henry Brown of Ludlow. They will continue the business at the former stand.

That G. W. Hiser, Lexington, Ill., has built an addition to his Hardware store, which will be used as a tinshop.

That the Hardware store of G. H. Blaker, Maumee, Ohio, was burglarized on the 19th ult.

That D. P. Noyes' Hardware store at Henniker, N. H., was recently burned out.

That the store of Wylie Bros., Elizabeth, Pa., was entered by robbers on the 20th u't., and about $100 worth of Hardware carried away.

That the wholesale Hardware firm of Logan, Gregg & Co., Pittsburgh, suffered slight damage by fire on the 20th ult. Spontaneous combustion is the supposed cause of the fire.

Current Hardware Prices.

JUNE 30, 1893.

Note.—The quotations given below represent the Current Hardware Prices which prevail in the market at large. They are not given as manufacturers' prices, and manufacturers should not be held responsible for them. In cases where goods are quoted at lower figures than the manufacturers name, it is not stated that the manufacturers are selling at the prices quoted, but simply that the goods are being sold, perhaps by the manufacturers, perhaps by the jobbers at the figures named.

The character @ is used to indicate a range of price; thus discount 50&10@50&10&5 % signifies that the goods in question are sold at prices ranging from discount 50 and 10 % to discount 50 and 10 and 5 %.

News and Notes.

The British Isles are suffering from a fodder famine, caused by the long drought. Hay is cabled from London as scarce at $40 a ton. The agricultural distress caused by lack of rain is widespread throughout Europe.

A military road, connecting the cities of Baltimore and Washington, is projected, to be used for the movements of troops in case of interruption to railway travel by riots, &c. The expense will be borne by the Government and the State of Maryland.

Forest fires in the Mesaba range have caused serious destruction of property in the mining towns and camps. Loss to the extent of $1,500,000 is spoken of.

The aspect of affairs in Australia appears, by last advices, to be brightening. It is thought the crisis has been reached and passed, and that any changes will now be for the better. The announcement that the Bank of England had decided to discount bills of Australian banks which have been strong enough to hold their own has caused a returning feeling of confidence. The London *Financial News* says, in regard to the situation: "Notwithstanding all that has happened in Australia—overspeculation, bad legislation, government extravagance and corruption, and everything else—the Australian colonies contain vast resources and are fully able to pay their way."

A recent statement issued by the Japanese Customs Bureau shows that the foreign trade of Japan is increasing more rapidly with the United States than it is with England, France or Germany. The increased exports to this country are mainly under the head of Japanese teas and silks. Direct imports from the United States in 1892 amounted to only $6,000,000, but this is a new and growing trade.

Official statistics show the export trade of New Zealand to be increasing at a very satisfactory rate. The principal product of the colony—wool—was exported to the value of $20,703,874 last year; frozen meat, a new and growing industry, shows $4,960,170 worth sent out of the islands in 1892. Gold exports reached nearly $5,000,000 in the same period. The other staple products, namely, butter, tallow, Kauri gum, wheat and oats, all show an increase; while flax exports fell off $335,000, as compared with 1891.

The Westinghouse Electric Company's charges against certain officials of the General Electric Company, and others, have been sustained by the Grand Jury at Pittsburgh, who, it is announced, found a true bill against the defendants. It is alleged that the persons accused conspired to secure blue prints and tracings, showing the design and construction of certain machinery owned by the Westinghouse Electric Company.

San Francisco papers say that the final trial trip of the United States coast-defense ship "Monterey" has developed the fact that she is a good seaboat, but a failure as a fighter. Her big guns wrecked their hydraulic machinery when fired but once, and if they were loosed for action in a sea they would tear the vessel to pieces. The fault is said to lie in the designs, and not with the builders, who carried out their contract faithfully.

The ship channel at Mobile, Ala., from the city wharves to the lower bay is to be deepened to 23 feet to allow vessels of 20-feet draft to load at the wharves. A project is also on foot for the construction of the Mobile, Jackson & Kansas City Railroad, which would be a valuable feeder to the port.

Southern farmers to-day are not depending solely on their cotton crops for a living. In the majority of States most agriculturists are raising diversified crops, and this practice is becoming more general every year. Cotton raising in Georgia and the Carolinas will, it is said, soon hold second place, as to value, among the agricultural products of those States, because of the increase in production of cereals, fruit and vegetables.

The beet sugar industry of this country is growing to be an important one. Last year's production furnished sufficient sugar for the average supply of half a million of the population. Great endeavors are to be made to extend and consolidate the enterprise.

The rumor to the effect that Secretary Carlisle purposed removing the United States mint from Philadelphia has been emphatically denied. The Quakers are at present agitated over the choice of a site for the new building in their city.

Advices from the West report the likelihood of short supplies of cattle and hogs for some time to come. The long and cold spring experienced in that section has reduced the number of young rising pigs, and litters are said to have been unusually small. Stocks of provisions on hand are, however, large; and as the generally depressed state of trade in Europe will tend to check exportation, there is no expectation of any present rise in prices.

The yield of the sugar orchards of Maine, New Hampshire and Vermont is about 70 per cent. greater than that of last year.

The aggregate value of the iron, steel, foundry and machine shop products of Paterson, N. J., last year was a little over $3,000,000, or nearly three times as great as that of the silk and textile industries for which the city is principally famous in popular estimation.

Two large screw passenger steamers for the Old Dominion Line are to be laid down at once at Roach's shipyard, Chester, Pa. They will be similar in construction to those previously built; the dimensions being 322 feet length over all; 40 feet beam, and 34½ feet depth; and the cost about $350,000 each.

The *Nautical Magazine* says that owners of steamers built of mild steel are beginning to find out that when subjected to heat and the action of acid it deteriorates much more rapidly than iron. In some cases, it is reported, the inner plating of the double bottom in the range of the engine room has corroded through in a very short time.

An exact measurement has been taken of the big gas well at Findlay, Ohio. The gauges showed that the well was producing 18,380,000 cubic feet of gas per day.

At a meeting of the United States Wheat Millers' League recently held at Toledo, Ohio, letters were read from American consuls in Europe and the West Indies offering their services in aiding the extension of foreign markets for American flour.

The probability is mentioned that some of the hop growers of New York State may introduce the cultivation of hops into North Carolina, portions of which State are said to be peculiarly favorable to the cultivation of the plant.

Over 1,000,000 acres of land for coffee cultivation have been sold in Mexico during the past six months, many Americans being among the purchasers. European syndicates are reported to have acquired extensive coffee lands in the States of Vera Cruz and Oxaca.

Sailors and others interested in shipping are to meet in London at an International Maritime Congress next month. Thirteen nations will, it is said, be represented.

LABOR EXCHANGE.

Notices under this heading of reasonable length are inserted free of charge. Only those relating to employment are admitted. Write distinctly on one side of paper only, and do not use postal cards.

Popular Disinclination for Manual Training.

In a recent conversation on manual training for boys, one who is interested in the management of a small trade school, lately established in connection with a New York church, complained bitterly of the unexpected difficulties he met with in obtaining the consent of parents for their boys to attend the manual training classes provided for them. The school in question is designed to cultivate a taste for handicrafts in the younger lads of the eastern district, in which the church to which it belongs is working. The idea is to prepare the boys for eventually joining one of the more advanced trade schools with a view to entering some useful and remunerative mechanical trade, such as carpentry, painting, plumbing, sheet metal working, &c. Instruction is gratuitous, and the hours are so arranged as not to interfere with the daily work of boys who may be in other employments. Everything is done to interest them by providing lectures and entertainments, in addition to the practical instruction. But notwithstanding these inducements the parents, although mostly in the poorest circumstances, do not care to have their children trained for manual labor. Their preference is that they should learn bookkeeping, or in some other way be fitted for clerkships or kindred occupations. There is a foolish and mistaken notion abroad, particularly among the poorer portion of the community, that there is a sort of "gentility" surrounding work in an office or a store which is not to be found in manual labor at the bench or the lathe. These silly people's ambition is to see their boys dressed in black coats, with nice white hands and linen instead of bearing the marks of honest and ennobling labor in a manual calling. They are not far-sighted enough to look ahead into the future prospects of either kind of work, and it is a difficult matter to persuade them that the best interests of their children mostly lie in the opposite direction to that toward which they incline.

Advantage and Dignity of Manual Labor.

Parents cannot understand that in training boys as mere writing machines or counter servers they are launching them on a market which is and always will be overstocked, while in fitting them for skilled labor they give them an education which, provided their moral and mental qualities are reliable, will insure for them steady and well-paying employment in the present, with the prospect of early independence and a position, when they have reached the upper rungs of their trade ladder, which not one in ten among the more stylishly appareled crowd of clerks can ever aspire to. The pecuniary advantages, present and future, of the skilled workman in such trades as are taught in manual training schools are in this way infinitely superior to those attaching to the average run of clerkships. But beyond and above this consideration there is, when rightly understood, a dignity and an ennobling character about the labor of the hands which recommends it to all honest and right-thinking minds as a thing to be admired, and which does not exist to the same degree in the so-called genteel occupations to which so many misguided youths of the poorer classes are devoted. "The dignity of labor," although a term too often prostituted to unworthy purposes by demagogues and agitators, so that to some noses it has acquired a stale and canting odor, is yet as true a phrase as ever gained currency. Like a golden coin it loses not one whit of its intrinsic value because it has been touched and used by unwashed or unworthy hands. This grand expression needs to be put up in its rightful position in the sight of all the rising generation who may be inclining to bow at the shrine of kid-gloved and stiff-collared gentility to the disparagement of the claims of honest and heaven-blessed manual labor.

Value of Sanitary Precautions.

The active precautionary measures adopted last year to prevent the introduction of cholera into the United States not only happily accomplished their object, but also appear to have had a wider effect for good than was calculated, in the prevention of general sickness in certain parts of the country where special sanitary work was done at that time. This fact is strikingly brought out in the report of the Michigan State Board of Health for the last quarter of 1892. This document records the fact of a remarkable decrease in the usual autumnal fevers, and generally through the entire list of diseases in that State, as compared with previous sickness statistics. This is attributed to the anti-cholera measures taken, and appears to signally verify the prediction of sanitarians that work to prevent the introduction and spread of cholera would be recompensed through the lessening of other complaints. In Michigan the precautions taken were of a particularly complete nature. All immigrants were medically examined and their baggage was disinfected at the border, thus lessening the chances of introduction of any communicable disease. The water supply, too, received special attention, and a house-to-house sanitary inspection was instituted and strictly carried out. To this preventive work the satisfactory result of lessened sickness and improved general health in the community are probably directly due, and it supplies evidence of the value and importance of those sanitary precautions which, when there is no imminent danger of cholera, are too often neglected. Whether the scourge is likely to cross the Atlantic this summer or not, it is too early to predict. Surgeon-General Wyman says, re-assuringly, that we have an even chance of escaping it, and that, even if it does come, our quarantine arrangements are so efficient that it is unlikely to become epidemic. It is sincerely to be hoped that these predictions will not lull the minds of State and municipal authorities into any such condition of supineness as would cause them to neglect any measures tending to secure immunity from cholera. As has been instanced in Michigan, sanitary precautions with this object will be well repaid by the beneficial effect they will certainly have on the public health. But they must not be undertaken in any perfunctory manner.

Value of Convention Papers.

A noticeable feature of the recent conventions of the master plumbers and fitters, held in Milwaukee and Chicago, was the number of interesting and instructive papers presented by the members, and which is a most encouraging sign, as it shows the sincerity with which the trade are supporting these associations. The primary objects of the organizations are of a commercial and business character, but now that they are getting well established and are carrying out the reforms and making the improvements in their trades that they have been working for, the members have more time and inclination to give to the educational features of the conventions, and are showing

a praiseworthy interest in the preparation of papers pertaining to their crafts. Each year we may expect to see a higher and higher level reached in these addresses, and the publication of papers of this sort by practical men will have a very wide reaching influence upon the trades and upon the regard in which they are held by the public.

New Enterprises.

The hard times are having an effect on the formation of new industrial corporations. The laws of some of the States, notably of Illinois, are very favorable for enterprises of a corporate character, and for some years past they have been launched at a rapid rate. The percentage of these resulting in genuine business undertakings and the actual investment of capital has been larger than would ordinarily be supposed. It was a comparatively easy matter to take a patented article, interest a few persons in its manufacture and start a company. Now, however, speculation in this direction has been checked by the scarcity of money, and the promoters of the few corporations being formed are having a serious time in securing financial backing. Meritorious schemes, as well as those wholly speculative, suffer alike under the grievous pressure now resting on business all over the country.

Education of the Body.

One of the greatest writers upon education, Professor Huxley, has put first, in his description of what constitutes a liberally educated man, a body that is "the ready servant of the will, and does with ease and pleasure all the work that, as a mechanism, it is capable of." The capacity of the human body, considered as a mechanism, has been very forcibly exemplified by the feats of the strong man, Sandow, who has been astonishing audiences in Europe and America by his remarkable strength. Being only 5 feet 8 inches in hight, and weighing only a little over 180 pounds, this wonderful athlete is by no means what one would call a large man; yet he has strength so much beyond what is usually met with in men of much larger frame and greater weight that, as regards muscular power, ordinary men are mere children in comparison. It is to be doubted, however, that the training of the body to its maximum of muscular power is the highest kind of physical training. This kind of education does not reach the point defined by Professor Huxley. It does qualify the human organism, considered as a mechanism, to do with ease and pleasure all of which that organism is capable. There are many things to be done in the work of the world that require delicacy and refinement of movement and touch, rather than massive strength, and this is especially the case in some kinds of mechanical construction. Here accuracy of movement, sensitiveness and precision are worth more than physical force. It is very questionable whether a man like Sandow, who can lift a heavy man from the floor on the palm of one hand, could ever regain that sensitiveness of touch necessary to the machinist in the operation of caliper-ing, or the precision of movement needed by a plumber in wiping a joint or in lead burning. The day is past when the mere brute force of a man has a high market value, except for exhibition purposes in roof gardens, dime museums and the like.

Chicago's Two Millions.

The claim is made by the Chicago newspapers that their new city directory, just completed, indicates a population of 2,000,000, if not more, within the city limits. The directory contains over 500,000 names, and the usual proportion in cities of such names to population is 1 to 4. This seems incredible, because it almost doubles the population within three years, or from the taking of the last United States census. Yet it is possible. All things are possible with Chicago. It is the phenomenal city of the world. Its officially recorded growth surpasses anything before known. This estimate may be reasonably correct. During the past year or two there has been tremendous growth in the manufacturing interests of Chicago. New manufacturing suburbs, within the city limits, have sprung up and grown at a very rapid rate, while the population of the built-up portion of the city has also increased visibly. It has been the subject of unceasing remark that the expansion of large office buildings barely kept pace with the demand for office accommodations, and an idle or tenantless store on any business thoroughfare was unknown. Advances in rents found somebody always willing to pay them. The World's Fair was responsible for some of this, of course, but not for all of it. Growth of population evidently was the great sustaining force. A city of two millions is a city to be proud of. We hope that the figures are correct when put to a stronger test than the estimate based on the directory.

Solvent Bankrupts.

The revolution of the wheel of time has again brought into distressful operation the law of the "survival of the fittest." There are variations, however, in the present application of this law which were not manifest to any considerable extent in previous periods of financial disturbance, and the term "solvency" has taken a new meaning. Heretofore an establishment has been considered solvent when its assets have exceeded its liabilities without regard to the immediate availability of the assets. Now, however, the lack of ready money, or the closing of an accustomed channel through which assets have been converted into cash, may force to the wall a great manufacturing or commercial enterprise with assets several times larger than its liabilities. Solvency to-day is the possession of the actual cash necessary to run a business; insolvency is the lack of such cash, without regard to the value of assets not cash. Establishments endowed with every qualification for a successful business career are for this reason being forced into liquidation along with the usual crowd of concerns that have been dragging out a miserable existence for years, and needed only a little unfavorable financial weather to carry them off. The situation calls for unusual forbearance on the part of creditors, to avoid the embarrassment of reputable establishments whose management can easily pull through the storm if not too sharply pressed.

Bad Collections a Blessing.

BY A. J.

Being on very confidential and intimate terms with one of my old customers, in corresponding with him I have sometimes mentioned matters in my business that either pleased or annoyed me, though not of special interest to him. Recently in writing him I wound up by saying, "Nothing new at present, but extremely worried over collections, which are very bad." In a day or two I received a letter from him, which, I think, might give some other fellow a hint and a help as it did me. I quote from his letter as follows:

I regret that you find collections slow, but right here is a chance for you to firmly establish some of the best custom you will ever have. By a kind, personal talk with many of these fellows, by giving them your confidence and telling them your needs you will get their confidence in return and some new ideas as well. Here is your opportunity; they don't know anything about business compared with what you know, and by careful attention you can learn their weak points, which will enable you to instill some of the simplest yet most important business precepts and principles into them. These simple foundations of business success are all that many of them lack, for they are industrious and even enterprising, but bad pay for the lack of something which they would gladly acquire if it could be secured without humbling their pride. With your fund of knowledge and wide experience nobody could better than you apply the remedy, but do it in such a way that he will remember you when your hints bear fruit, of which, it is needless to say, your share will not be withheld. Inquiry into the inner affairs of a man's business requires tact. If done conscientiously and a fearless recommendation is given of the needed reform, it will gain you a friend, as well as secure firmly a customer, who will pay better as the plans suggested progress. The reason it is so hard to sell goods to some men who are dealing with another house is more frequently than you have any idea due to just such a past history. To keep your temper and be generous and just under the exasperating influences of tight money and bad collections with men whose business methods are stupidly and radically wrong is difficult, I know. If, however, you are equal to the strain you will be successful in time in making slow payers prompt payers, and the outlay of vitality and mental effort will bring big dividends. It takes a man of wide experience, great ability, generosity and gentle firmness to collect from slow payers and reform them, but it pays to study and fill these requirements. Such a condition in the majority of cases is due to selling your customer more than he can dispose of, and then he is entitled to great consideration from the seller.

STEAM AND HOT WATER.

The Efficiency of a Low Radiator.

BY C. K. PRINCE.

In the use of direct radiation there is a point which, it would seem, is not generally known to the trade, or, at least, if known, is not often recognized or made use of. This point is the increased efficiency which is secured from a low-hight radiator over one of the standard size. The proportioning of the radiation is a detail in the planning of an apparatus for warming which will call for the most careful judgment of the engineer, and it is important that a full consideration be given to all conditions which would influence this estimate, forming, as it does, the basis of computation for the entire work, and particularly for determining that most vital point in any system of warming—the boiler.

The calculation of the amount of radiation to employ for certain work is too often made, practically, a mere matter of guess, but to secure uniform and satisfactory results in this direction a definite and proper consideration must be given to existing conditions, and allowance made for certain detail of the proposed work, such as the character or style of the radiation to be employed, its position, the temperature at which it is designed to carry it, and other features of a similar nature, which have much to do with the success or failure of the work, and a disregard of which (excluding a possible piece of good luck) will insure an ill-balanced and unsatisfactory apparatus.

So far as the style of radiation to be used is concerned, it would frequently seem to be the best way of disposing of the surface in some rooms to put it in the shape of a low radiator, the only objection being that there is not always space enough to permit the placing of what has been decided to be the requisite number of feet, which has been previously determined on the basis of a standard-hight radiator. Has the idea never presented itself that a low radiator was a considerably more efficient arrangement of the heating surface than when in the form of a radiator of the standard hight? Or, in other words, that it would take less surface to do a certain work when this surface is disposed as in a low radiator than would be required were the surface in the form of a radiator of the standard dimensions.

That there is this increased efficiency in the use of low radiation can be readily shown, and the idea may prove of interest and value to the fitter. The reasons are plain and can be readily grasped. The explanation rests on a principle recognized as one of the laws of heat, to the effect that if two bodies of different temperature be placed adjacent or in contact, heat will pass from the warmer to the cooler body until such time as an equilibrium shall be established, and both bodies represent an equal temperature. The amount of heat thus passing in any instant of time to be the greater, the greater the difference in temperature between the bodies. Now in the case of the direct radiator the large part of the heat given out to the room is by convection—that is, by direct contact of the air in the room with the surface of the radiator. The air being cooler than the radiating surface, the heat from the radiator is imparted to it in accordance with the terms of the above laws.

In the circulation thus established by the direct radiator, the colder air at the bottom of the room, meeting the warmer surfaces of the radiator, absorbs some of its heat and begins to rise along the length of the column with an increasing velocity and a temperature which approaches nearer and nearer to the temperature of the radiator, and finally passes off the radiating surface into the circulation of the room. That part of the passage of the air at which the conditions were the most favorable for the absorption of the greatest amount of heat is at the beginning, when the difference in temperature between the air and the surface is greatest and the ascending current of air has its lowest velocity. As it rises the increase of temperature increases its velocity, and the conditions existing during the latter portion of its contact with the radiator are obviously less favorable for the transfer of heat to the air than have existed at any time in its passage. Therefore, it is plain that the larger part of the work is done during the first part of the contact of the air with the surface, and consequently it is done by the surface at the base of the radiator.

Does it not follow that we are in a better position for securing the highest efficiency from our surface when every foot is placed as near as possible under the best conditions for the absorption of the greatest amount of heat by the air, or, in other words, placing it in the form of a low radiator? Furthermore, are not pipe coils recognized as being the most efficient form of heating surface which we employ for warming? Are not the reasons given above in favor of a low radiator the same which will account for this superior efficiency of the pipe surface? Are we not, in using low hight radiation, placing our surface in a form which resembles pipe coils more and more the lower the radiator which we employ? May we not, therefore, expect that in thus approaching a pipe coil in form and arrangement of our surface we are approaching its efficiency in a like measure?

The position in which a low radiator may be placed is also an argument in favor of their more extended use. There can be no question but that the most favorable spot in a room for placing direct radiation is exactly under the windows on the exposure. There is always a strong down current of cold air before the window, and in placing the surface where it can meet this movement before it gets into the circulation of the room gives an opportunity of checking the current which would otherwise pass downward constantly, maintaining a flow of cool air over the floor and forming a consequent source of annoyance and discomfort.

This same point, in regard to the absorption of a larger part of its heat by the air during the first instants of its contact with radiating surface, may be noticed in the use of indirect radiation. Here it is a well-known fact that there is no marked difference in results to be obtained by arranging the radiators in a double tier and causing the air to pass over twice the usual extent of surface. The reasons are that the 6 or 8 inches of warming surface in the first tier of radiators is a sufficient distance to afford opportunity for a thorough warming of the air, and the second tier, receiving the air under so much less favorable conditions for the imparting of any further amount of heat, has but little chance of making any marked difference in the results obtained. This would apply only in cases where a natural circulation of the air is sought. If a mechanical circulation is used, the increased velocity of the current would require a considerable extension of the heating surfaces. The conditions under which an indirect stack is working do not differ to any great extent from those of the direct radiator, so far as the matter in hand is concerned, and this fact may be allowed to put in its evidence in favor of the increased advantage of the disposition of radiating surface in low radiators.

The main argument, of course, against their more extended use is in their cost, but in point of fact the increase in efficiency keeps pace very nearly with the increased cost and thus tends to make all hights equally expensive. In most instances, too, there can be little question but that a low radiator can be made to make a much more presentable appearance in a room than any other arrangement of direct-heating surface, and this, with an understanding of their increased efficiency and consequent lowering of price, should lead to their more general introduction.

English Practice in Hot-Water Heating—XXV.*

JOINTING AND SUPPORTING PIPES.—CHIMNEYS.

The general method of jointing hot-water pipes, when there is a large number of joints to be made, is by what is known as the rust joint. For small works there is now a more general application of the rubber ring, or some of the different forms of expansion joints, these latter being now made in considerable variety and having many good features. Joints are also made with red and white lead and yarn, but this is a more expensive joint; it, however, is not so rigid as the rust joint, and fulfills a use in this respect, as will be seen directly. It is a joint also used with small works, as the little extra expense is then trifling, and it is convenient both in application and in obtaining the materials. The rust joint is cheapest, but not convenient, unless the works are on a large scale, or several jobs are being carried on at once. There are several other different joints, workmen

* Reprinted from the *London Builder*.

sometimes making a joint specially their own. The writer once saw a joint made with old tarred cord and nothing else, and this withstood a pressure of 30 pounds per square inch.

There is a distinction between horticultural and building works in the question of joints, in the fact that the former, in having no hight, produces no pressure, and almost anything will make a water-tight joint, if it does not make a lasting one. With building works, the pressure, if the hight be anything to speak of, quite precludes the use of the plain rubber ring, and the other joints (rust, &c.) must be allowed to set thoroughly hard before the apparatus is charged. This, it is understood, applies to cast-iron heating pipes and coils; what wrought pipe may be used has screwed joints, and will bear very heavy pressures.

The rust joint is made by mixing iron borings (these can readily be procured at about 9 shillings per cwt.) with some sal-ammoniac and sulphur in a powdered form. The addition of these two latter materials to the borings causes a chemical action to set in, and the iron rusts into a hard and solid mass. The rusting process takes place quickly, but it is some days before the action entirely ceases, and this brings about very disagreeable results when the workman is not experienced. The borings, during the change they undergo by the addition of the two substances named, expand somewhat; that is to say, the mass of material exerts an expansive force while the chemical action is proceeding. The result of this is that, as the action chiefly takes place after the borings are calked into the socket, there is every probability of the socket splitting if the joint is not made by a skilled man. There have been vast quantities of pipe spoiled in this way, and it is somewhat fair evidence of experience when a man makes rust joints which remain sound and do not injure the sockets.

Workmen have different ways of calking in this material. The socket is, we may say, never filled with borings only; there is always some yarn used. Some workmen calk the socket half-full of yarn, the remaining half with borings; sometimes it is three fourths yarn just finished off with borings, or it may be the socket is packed with two or three alternate layers of the two materials. A good workman makes his joint quite water tight with the yarn alone, but this material needs sustaining with the iron borings, which go to complete and make the joint permanent. Two-thirds yarn and one-third borings make a good joint.

The proportions of the materials added to, say, 100 parts of borings, are one part powdered sal-ammoniac and two parts powdered sulphur, the whole being moistened and thoroughly mixed. It requires to be made from one to two hours before it is used, but the weather will affect it in this respect. It cannot usually be kept longer than one day without becoming hard and unfit for use.

The red and white lead joint is made by taking the latter material, which is a sticky mass, and adding the dry red lead to it until the mixture is of the consistency of putty. Some of this mixture is taken and has boiled oil added until it is quite liquid, and the ends of the pipes are painted with this, otherwise the putty material will not adhere. Usually the joint is made by calking in alternate layers of yarn and lead, the yarn first and finishing with the lead, and when dry it is a sound and durable piece of work.

The rubber-ring joint is now considerably in favor, as it has many good features, chiefly by its convenient application to certain purposes. A considerable trade is now done in small boilers, which are sent out for amateurs' greenhouses, complete with the pipes, &c., and are so constructed that the purchaser can erect the whole of the apparatus himself. The joints of these pipes, both with the boiler and with one another, are commonly made with a plain rubber ring, and for this purpose it is a great convenience. Then, again, in some large works temporary lines of pipes are sometimes needed, and for this purpose the rubber ring is a positive boon, as it can be used with any ordinary description of pipe. Occasionally permanent works of a large character are carried out with this joint, but it is not a usual practice.

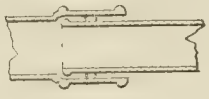

Fig. 101.—Section of Rubber-Ring Joint.

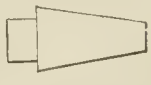

Fig. 102.—Tube Expander.

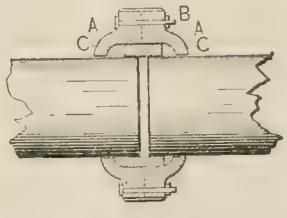

Fig. 103.—One Form of Patented Joint.

The particular convenience of the rubber-ring joint is the expeditious way in which it can be used. It consists of a ring of round india rubber, full ⅛ inch thick, the size varying with the size of the pipe, of course. This ring, which is a little smaller than the pipe, is stretched just on the spigot end of the pipe, and this is then forced into the socket. Its passage in causes the ring to roll, and by the time the spigot is pushed home the ring joint is half way up the socket, as Fig. 101 (section). Instead of stretching the ring on to the spigot, a ring expander can be had, which, when one end is placed in the pipe, permits of the ring being rolled up in it on to the pipe, and this prevents it being put on in an irregular manner or twisted. The tube expander is as Fig. 102. This joint is totally wanting in rigidity, and the pipes need to be well supported.

This and the following joint are what is termed "expansive." What is really meant is, that it is elastic, and considering that every variation in the temperature of the water brings about a movement in the pipes (expansion and contraction), the necessity of such a joint becomes obvious. With the rust and also the red and white lead joint some provision is always made for this, if the pipes extend any distance. With short services no provision is needed. With the two joints named a long, loose socket is provided here and there, and so packed that the pipes can move to and fro in it to a trifling extent. One firm of growers use rust joints, but use a rubber ring for every sixth joint. The expansive force is not extensive—that is to say, in a 100-foot run of pipe we may never get more than 1 inch total extension in length, but the force is certain and irresistible; so much so that brick work bas often been displaced by the thrust. The rubber joints allow for this, and act very successfully.

There are several forms of patented joints that have rubber as the jointing material, and which possess the elasticity just spoken of. It is not necessary to describe them all, but Jones'

Fig. 104.—Iron Supports for Pipe.

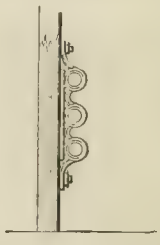

Fig. 105.—Method of Fastening Pipe to Wood Work or a Wall.

Fig. 106.—Roller Supports for Long Runs of Pipe.

ENGLISH PRACTICE IN HOT-WATER HEATING.

patent, as Fig. 103, can be described as an example. This consists of two cast collars, A A, an iron ring, B, two rubber collars, C C, and the whole brought together with the bolts shown. This joint has the advantge of being used without socket or special shaped ends to the pipes; any plain pipe can be jointed, and if the pipe was badly or roughly cut a joint might still be well made. This saves waste of cut pipe, as some of the patented joints depend upon one of the ends being made to suit the other. A joint like this, Fig. 103, permits of any length of pipe being taken out and replaced with new if needed without disturbing the remainder. This would prove very convenient if, after laying down a long run of pipe, a bad leakage was found somewhere in the middle. With the ordinary joints a mishap like this is provided for by putting running—*i. e.*, loose—sockets here and there. All kinds of rubber joints are more expensive than the rust joint, but if any one wishes to compare the cost between the two, let it be remembered that a rubber joint can be made in an exceedingly short space of time.

Pipe Supports.—In nearly all horticultural works the supports are little piers of brick work, and for such purposes nothing better is needed. It is essential that the brick piers be on a good foundation, or their own weight and the weight of the pipes may cause them to sink, with the most disagreeable results, even if the joints in the pipes did not become fractured. For those situations where the pipes are seen iron supports can be used, these, as Fig. 104, being of better appearance and very safe. They are also exceedingly cheap, being mere plain castings. When pipes are carried along a wall or wood work they are sometimes strapped on, as Fig 105. There is nothing unworkmanlike in this.

When the runs of pipe get somewhat extensive, then, in addition to elastic joints, there must be some provision on the supports themselves to allow for the movement that takes place. With brick piers a piece of small iron pipe or round rod iron will form a frictionless bearing ; or if iron supports are used, they can be purchased, as Fig. 106, or a smith can make something with rollers for the pipes to rest upon. If such a provision is not made, there is every probability of some harm ensuing. But, as just mentioned, this need not be thought of with medium and small sized works.

Chimneys.—Reference has been made to these from time to time in the previous papers, and very little remains to be said. We have fully pointed out the necessary features with chimneys in building works, but there needs to be given the rules usually followed in making the chimneys to boilers attached to glass-house works, those which stand away from buildings. In giving the following sizes it is supposed the chimneys are brick built, not sheet-iron pipe. Earthenware pipes, however, answer very well for this purpose as a rule.

The minimum hight of chimney should not be less than the length of the flues that lead up and down the boiler; that is to say, a 4-foot saddle boiler, having flues once up and down its length, should have an 8-foot chimney. If the boiler was one having the flues traversing its length three times, then it should have a 12-foot chimney. Let it be clearly understood that these are the minimum hights. If we made the chimney of less hight than this, the draft in it would be insufficient to carry away the smoke or gases and cause a proper degree of combustion in the furnace. Sometimes a chimney a little lower will work passably well, but it is best to calculate as just described for a minimum hight.

Every opportunity should be taken to have a higher chimney wherever possible; better and more reliable results are attained; but of course in private gardens the chimney, beyond certain limits, is strongly objected to on account of its unsightliness in most cases. With professional growers sightliness may probably be the last thing to be considered—profit has more consideration—and higher chimneys are the rule.

The area of the chimney should bear some relation to the size of the boiler, and the following sizes are reliable:

	Area of chimney in square inches.
For Trentham boilers 8 to 10 feet long..	400
For saddle boilers 6 feet long.....	300
For saddle boilers 4 feet 6 inches long..	250
For saddle boilers 3 feet or smaller....	200

These areas are for the minimum-hight chimneys just referred to. As the hight is increased the area can be reduced. For low chimneys the area cannot be too roomy, it is essential, and at the point where the flues from the boiler enter the chimney the passage should not be choked in any way. It will be understood that as the hight of chimney is increased the draft is more keen and a less area will answer, but small area must be avoided with very low chimneys. If the hight of chimney was double the minimum given, then the area could be reduced, say, one-fourth.

HEATING NOTES.

The United States Heater Company, Detroit, Mich., are distributing among the trade a postal card, upon the back of which are several illustrations of radiators for steam and hot water. The engravings show ordinary curved and dining room radiators, while reference is made to column, corner, window, stairway and low and extra high radiators.

W. H. Pennell, the hot-water engineer of the Model Heating Company of Philadelphia, is a delegate to the Christian Endeavor Convention at Montreal, and will visit his friends at his old home in Boston on his return trip.

The Richmond Stove Company of Norwich, Conn., have just issued from the press a very neat catalogue of a size convenient to carry in the pocket and relating to the steam and hot-water heaters which they manufacture. The little volume of 80 pages of printed matter is bound in red leather covers with a side title in gilt letters. The matter consists of illustrated descriptions of the several lines of heaters made by the company, together with tables giving valuable information in connection therewith. There are suggestions to the fitter, a statement of some of the causes of failure of heaters to operate satisfactorily, a specification and contract for the Richmond steam heating system, pages of memoranda of radiators and of trade discounts, as well as suggestions in estimating. A useful feature of the little work is found at its close, in the shape of a number of blank pages which may be found useful for a variety of purposes.

Knight & Jillson, Indianapolis, Ind., a large and pushing firm in steam, gas and plumbers' supplies, have recently secured a store adjoining their old stand. The new addition is two stories and a basement, 60 feet front and 100 feet deep. Steam gauges, National Tube Works wrought iron pipe, solder, hose, pumps, lead pipe, fittings and brass goods in full line leave no order unfilled, whether from the natural gas fitter, steam and hot-water fitter, mill and factory man or plumber, either in large or small quantities.

The Richmond Stove Company, Norwich, Conn., issue an illustrated and descriptive catalogue of the Richmond sectional heater for steam or hot water which they manufacture. On the front cover of the pamphlet a general view of the heater is shown. In the introductory pages the advantages of the Richmond sectional heater are dwelt upon, then a description is given, with illustration, of the brick-set form, followed by similar accounts of the portable forms of heaters for steam or hot water. Later on a sectional view of the apparatus is given, then a view of the grate and likewise of the separate sections of which the heater is composed. Tables give all dimensions, capacities, prices, &c., while at the end is a long list of testimonial letters and brief reference to some of the other Richmond heaters.

The firm of Pancoast & Maule, dealers in tools and steam supplies, Philadelphia, were dissolved July 1 by mutual consent of the partners. The firm had been carrying on business for 23 years, although the partners, Henry B. Pancoast and Francis I. Maule, have been business associates for 31 years. The business of the late firm will be settled by Henry B. Pancoast, who will also continue in business in the same line, at the old stand, under the firm name of Henry B. Pancoast & Co.

The Retailer's Opportunity.

In the present financial condition of the country complaints are frequently heard of the difficulty of making collections, and many manufacturers and wholesale merchants are a good deal inconvenienced, if not positively embarrassed, by the tardiness of their customers in the matter of remittances. This perhaps in many cases cannot be avoided, as retail merchants find it a difficult matter to collect their accounts, inasmuch as their trade is affected by the conditions which prevail so generally in the financial centers.

In many cases, however, retailers are not directly or very seriously affected by the financial distrust which prevails in other parts of the country, and by giving careful attention to the matter of collections, and by a little special effort in this direction they might be enabled to make prompt payments for their purchases. In this connection it should be remembered that at a time like the present the prompt payment of bills on the part of retailers who come directly into contact with the consumers will do something toward relieving the stress of the situation, and will put the large distributors of goods and the manufacturers in a more easy financial position. Something will thus be done toward improving the commercial situation and bringing about a more satisfactory condition of things.

There are many retail houses who take a commendable pride in meeting their obligations promptly and paying their bills as soon as they are due. This class of purchasers are, it is needless to say, regarded with more favor by those from whom they buy than others in the trade who are careless in this matter, letting a ten-days' invoice run for 20 or 25 days, and making a tardy remittance two or three weeks late for goods purchased on 30 days' time. Prompt payment is recognized as doing much to make the purchaser solid with the seller and entitling him to close figures, the best attention and any special favors which may reasonably be expected.

At the present time and during the past month or two we know that some retail houses have found it necessary to make unusual efforts to settle their invoices on maturity, but they have regarded it as a matter of pride and almost of honor to send their drafts as usual when the account has become due and payable. If they have not in all cases been able to do this they have sincerely regretted it, but their regret has been tempered by the reflection that they used every effort and were prevented only by the very exceptional financial conditions existing.

We are led to refer to this matter to impress upon retailers throughout the country that the present financial stringency gives to them an opportunity which is not afforded in times when money is easy. Promptness in payment, always appreciated, will be doubly appreciated now, and the heart of the jobber or manufacturer will be warmed toward the retailer whose remittances come on time.

ROOFING AND CORNICE.

Laying Steel Roofing.—IV.*

BY L. S. BONBRAKE.

FINISH AT EAVES AND GABLES.

Several plans are used for eave finish, among which we find the most common is to allow the metal to project $1\frac{1}{2}$ inches over eave board beyond the end of seams. Turn projection down as in Fig. 22, and nail 1 inch above extreme end, at intervals of from 2 to 3 inches, after which the 1-inch tongs can be used to turn the end slightly outward, as in Fig. 23, thus throwing the water away from the building.

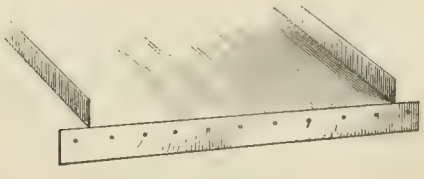

Fig. 22.—Eave Finish.

Fig. 23.—Eave Finish with Outturned Edge.

Fig. 24.—Edge Folded Back on Strip.

Fig. 25.—Edge with Second Bend.

can be avoided by either raising the edge with a wood strip, or a guard can be formed entire from the roof strip, by turning the metal wrong side up, and throwing a 2-inch edge backward upon itself the entire length of roof strip. Then return the metal, and with the 1-inch tongs form a T-flange from the folded edge, Fig. 27. To accomplish this the sheet must be raised or lifted slightly when turning the flange. It will be understood that when seams are to be formed and edges turned, except at hip and combs, the strips are notched or cut to the depth of the seams, and back on the metal to a point the width of the edge to be turned.

When solid sheeting is not used for a surface on which the metal is to lay, it should be solid at least a foot from

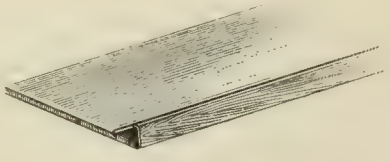

Fig. 26.—Edge Nailed to Eave Board.

Fig. 27.—Tee Flange Formed from Folded Edge.

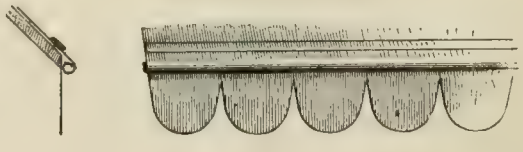

Fig. 28.—Enrichment Finish for Roof.

LAYING STEEL ROOFING.

Another form is to first turn the roof strip upside down, then turn an edge, or fold, with 2-inch tongs, back upon the sheet, as in Fig. 24. Then, with the inch tongs, turn an edge at right angles with the strip, as in Fig. 25, and when the sheet has been returned to its proper position a projection will have been formed, which can be nailed to eave board, and will prevent water from passing over the nail heads, as in Fig. 26.

The same result can be obtained by nailing a separate strip of metal around the entire eave, allowing it to project the distance desired. The roof strips can be hooked or secured by forming an edge over and under the projecting strip.

The roof at the gables of a building is ordinarily finished by turning an edge on the metal at right angles with the 1-inch tongs, and nailing as at the eave. At times, however, trouble has been experienced from this way of fastening, from the fact that if the roof should dip toward the gables the rain will run over the edge and blacken the cornice, forming streaks that spoil the effect of paint. This the eave up the roof, to provide a place for nailing when hanging the gutter. A board should be used along the comb, and hips and valleys should be sheeted solid, in order to finish the seams smooth and evenly.

A neat and practical manner of finish for roof at the edges of portico or ledge, and one that will prevent water from passing over cornice, is to nail an enrichment around the edge, of width as desired for down projection. Form a bead upon a strip of metal, and allow it to project over the enrichment, and back upon the ledge 1 inch, as in Fig. 28, with edge turned, under which it can be nailed, and to which the roof can be hooked and fastened. If it is not convenient to get enrichment, an ordinary piece of scolloped metal, which will answer every purpose, is easily made, and if properly painted presents a handsome appearance.

Nails should not be driven through or exposed on the surface of a roof. Soldering over nail heads is but a temporary arrangement, as expansion and contraction will draw the metal, burst the solder and cause leaks. In conclusion, we cannot refrain from making mention of an item we have read in almost every roofing catalogue that has

* Copyrighted, 1893, by L. S. Bonbrake.

come under our observation, to wit: "Our roofing can be easily understood by any ordinary mechanic, carpenter or builder, and can be laid by an inexperienced workman."

This may be true. But how is it laid? With seams gaping open up the roof; nails driven through seams in the body of the roof, to make them lay flat; the comb straddled and pounded full of nails; the eave not nailed at all, or, worse yet, nailed from the top of the roof. With all these, if the roof should leak, it is the fault of the material (?).

It is as important to have a skilled workman to lay a perfect steel roof, no matter of whose make it may be, as it is to have skilled artisans to provide the steel from which the roof shall be made. A diversity of plans of construction has provided simplified forms of laying. Yet the skilled roofer, whose business it has been to study his work and educate himself to meet the many difficulties as they arise, is undoubtedly better qualified to lay a steel roof that shall give entire satisfaction to all concerned than a workman in some other vocation.

If the roof is well and properly laid it is an advertisement tending toward the advancement of the steel roofing industry. If poorly laid it is yet an advertisement, but for the use of some other material.

(THE END.)

Paint for Exposed Iron Surfaces.

From X. X.—In *The Metal Worker* of June 10 under the heading "White Lead Paint for Tin," you quote a correspondent "as doubting if anything will beat a good coat or two of white lead and linseed oil." I have had some experience with graphite paint and do not believe any paint made can equal it for durability and preservative qualities when applied to tin or shingle roofs, tin leaders, and tin or iron work generally. A durability of from 10 to 15 years is claimed for this graphite paint on tin roofs, and one who has used it says he has a roof which he painted 20 years ago with it and repainting is not yet necessary.

FLASHINGS.

J. FOERSTER & SON, 806 East Fifth street, New York, have recently completed the tin, slate and copper work on the Roman Catholic Trade School, Madison avenue, Fifty-first and Fifty-second streets. The work also includes the galvanized iron ventilating shafts running from all the classrooms. A special feature of the sheet-metal work on this building is the copper work, which includes the finials, crosses, dormers and a large bay window on the rear of the building, the Gothic panels of which are entirely hammered by hand.

THE METAL STAMPING & SPINNING COMPANY of Grand Rapids, Mich., have recently begun the manufacture of architectural ornaments, making special designs. They also turn out copper and brass work, and make a full line of non-rusting goods, which they guarantee to be rust proof. A circular just issued by the company gives a number of illustrations of the company's goods, such as finials, balusters, rosettes, capitals, moldings, corner pieces, urns, kitchen utensils, milk cans, &c.

THE LONG STEEL ROOFING & CORRUGATING COMPANY of Indianapolis, Ind., during the past three months have made material increase in their facilities for supplying the trade, having moved to new quarters and doubled their producing capacity for steel roofing, siding and ceilings. They are furnishing for the Electric Car Company of Brazil, Ind., a standing seam steel roof of 200 squares, an imitation brick front and corrugated siding for their building. A shipment of roofing and siding has been recently made to a large flour mill and grain elevator in Arkansas.

THE SEMI-ANNUAL MEETING of the National Iron Roofing Association, which was to have been held on July 11 has been postponed to July 18, the place of meeting being the Hotel Plaza, Piqua, Ohio.

Prize Competitions

$25.00.

The following competition is yet before our readers and will remain open until the date named:

Prize Competition No. 27.

SUBJECT:

Local Associations of Merchants.

It has been found feasible to form associations in many places for the purpose of securing more friendly relations among competitors and reaching an understanding in regard to matters of common interest. Among the good results referred to as coming from such associations are the following: Overcoming petty jealousies; cultivating a spirit of fraternity; listing of undesirable customers; an understanding in regard to time of presenting bills; putting in operation early-closing movements; agreement as to the prices at which goods are to be sold; mutual accommodation in supplying goods which one merchant may be temporarily short of, &c. The subject is thus evidently a broad one and of a good deal of practical interest. In discussing it the following points are suggested:

Whether it is desirable to have such associations;

How such associations may be organized;

The objects to be accomplished by them.

It will also be of interest to have any information in regard to the practical working of such associations.

This competition will remain open until July 8, 1893.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which, in the judgment of the Committee of Award, are most suitable for publication and of the most general interest

We reserve the privilege of extending the time on the competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. This competition is open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than the dates on which the competitions close. They should be addressed as follows:

DAVID WILLIAMS,
96-102 *Reade street,*
New York.

Prize Competition No. 27.

The committee to whom the contributions in Prize Competition No. 17 were referred have awarded the prizes as follows:

First Prize to M. W. CARLETON, Cleveland, Ohio.

Second Prize to L. W. SPRAGUE, Greenville, Mich.

Third Prize to W. T. WARSOP, Fairport, N. Y.

Foreign Patents in Italy.

In the Italian patent law of 1859, says an English exchange, two kinds of patents are mentioned—namely, "Patents of Invention" and "Patents of Importation." Some time ago the question was raised before the Italian law courts as to whether an Italian patent for an invention already patented in a foreign country, and taken out as a patent of invention instead of as a patent of importation, would be valid. In two cases the Court of Cassation of Turin decided that such patents were not valid, and in another instance the Court of Cassation of Rome decided that they were valid. The Court of Appeal of Turin subsequently gave a similar decision as the Court of Cassation of Rome, and as the question was again brought before the Court of Cassation of Turin the latter recently gave its decision, canceling its two prior decisions and admitting that Italian patents for inventions already patented in a foreign country are valid whether they are taken out as patents of invention or as patents of importation. This is a question of great importance, for had the former decisions prevailed the large majority of Italian patents taken out by foreigners would have been void, they having been generally always taken out as patents of invention. The only difference between a patent of invention and a patent of importation is that the former can be granted for a period of 15 years, while the duration of the latter is limited to the number of years for which the prior foreign patent has been granted, not exceeding 15. With an application for a patent of importation it is necessary to file an official copy of the prior foreign patent vised by the Italian Consul.

Camels are coming into use in large numbers in connection with the mining industries of South Africa, as they are found to be impervious to the insects and diseases which prove fatal to horses and bullocks in that country. In Australia, too, the camel is fast superseding other draft animals in the barren deserts of the interior.

THE LETTER BOX.

Business Directory.

From L. M. W., *Delaware, Ohio.*—For some time back I have been making up a business directory, and send in my plan for the benefit of your readers. Whenever I see an advertisement or a notice in *The Metal Worker* in Odd Plates, Traps and Vents, Trade Notes, or anywhere else in the paper, of a house dealing in or making a specialty of some particular article or line of goods, I cut it out. Then I paste them in a book which I arranged with a double index. The first index is an alphabetical list of different articles, as stoves, tin plate, tools, supplies, &c., and from it I can see that sheet iron is on pages 12 and 13, where I have pasted all the different clippings that make reference to sheet iron. In the back of the book is another index with the name of the firm, and opposite it the page where the clipping which refers to them can be found. Often one advertisement or notice is entered in the first index under a dozen different heads, so that a firm which sells solder, steam valves and pipe wrenches, besides many other distinctly different things, can be easily traced. Of course, the clipping can only appear in one place, but on the pages devoted to each of the other heads a note tells where the clipping is to be found and to what house it refers. It has not been much trouble to keep the book, and it is far more convenient than to hunt over a file of the paper. After a season specially devoted to one line of work, much of the necessary information of other lines that would, naturally, be forgotten is securely stored here. As a directory of unusual goods, for which there is an occasional call, and which are a little out of my line, it is simply invaluable.

Trouble with a Well Cooler.

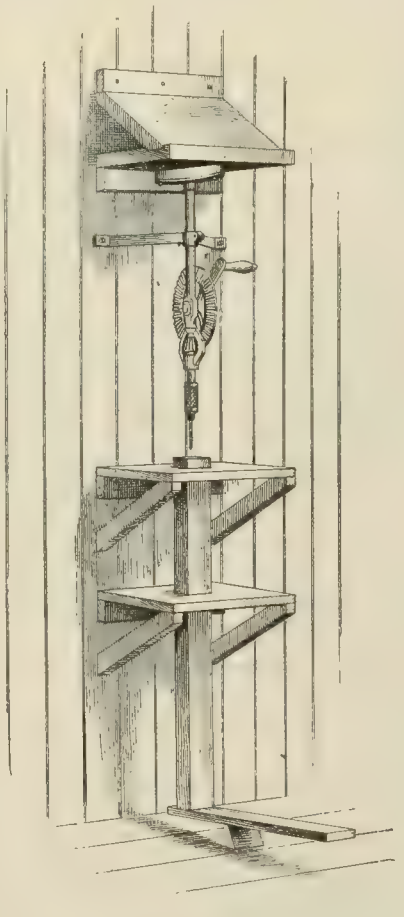
From E. H., *Nyack, N. Y.*—With regard to the well cooler of "P. R. F.," mentioned in the issue of the paper for July 1, I would say that if there is nothing in the boiler to prevent it, the warm water will follow a direct line from the inlet to the outlet pipe without circulating through the cold part of the boiler. By extending the inlet pipe nearly the length of the boiler inside and extending the outlet to nearly the other end the trouble will probably be overcome. Great care, however, should be taken to have the outlet pipe draw the water from the bottom of the boiler.

Laying a Flat Tin Roof.

From J. H., *Harrisburg, Pa.*—I notice in *The Metal Worker* of July 1 an inquiry from "C. S. P.," with regard to the best method of laying a flat tin roof. According to my way of thinking, the best plan is to put the tin together in rolls of, say, 28 sheets. Care should be taken to have the tin straight and then turn up 1 inch and cleat down well, say one cleat about every 6 inches, and two nails in each cleat. Then use a pair of $1\frac{1}{4}$ tongs, turn up, and then take a small seamer and single seam tight. Hammer down and solder, and the result will be a good roof. A satisfactory job will not result if one sheet is put down at a time. The plan described is the way I follow, and I have in mind a roof I put on 20 years ago, and it is as good to-day as when the roof was laid. I would also say that there has been no repairing done to it. The correspondent says that his roof is 50 x 80, with a fall of 4 feet in 80. I would say that when he gets within 20 or 25 feet of the top he can make a standing seam, and flatten up that far.

A Sensible Drill.

From C. E. M., *New Jersey.*—Knowing that in many shops there is no regular upright drill, and that its need is



A Sensible Drill.

sorely felt when a breast drill is the only means of drilling a lot of holes in an old stove plate which has to be mended, I send you a sketch and description of how I have made my portable breast drill do good service as a stationary drill. Against the plastered wall I found a stud by hammering, and to it at right angles I fastened a piece of 2 x 4 inch white pine extending out 18 inches, with a notch in the top side to hold a brace of the same material, which was also fastened to the stud and a cleat fastened over it so as to prevent the outer end from raising when the strain comes on it. I drilled two holes in the breast plate of the drill and with screws fastened it to the horizontal brace. To hold the drill true in position two iron braces $\frac{1}{4}$ x $\frac{5}{8}$ inch were bolted to it, running off at an angle to the wall, where they are fastened to other studs. By unscrewing the one bolt in the braces and the two screws in the breast plate the drill can be quickly removed to be used on work that cannot be brought to it. Under the center of the drill is an upright piece of solid wood 3 x 3 inches, which works plumb up and down through neat holes in two other braces which are fastened to the wall in a manner similar to the top brace and very securely, as on their being true depends the true working of the upright. The upper end of the upright is within 2 inches of the drill bit, while the lower end rests on a lever at the bottom, the lever working over a triangular piece of hard wood, as shown.

By placing the work to be drilled on the top of the upright and one foot on the lever the work can be forced up against the drill with the desired force, while the drill can be turned by hand. Having secured excellent service with my device, and thinking some others might appreciate its value, I tender it for the appropriation of all who desire.

North Pole Ice-Cream Freezer.

From H. & B., *Allentown, Pa.*—Will some one please tell us through the columns of the paper who manufactures the North Pole ice-cream freezer?

A Water Back Question.

From W. F. S., *Bayfield, Wis.*—Please help me out in a matter that has given me considerable trouble. I put in a bathtub for a customer, and as they had no range for heating the water but a large No. 10 common cook stove I made a water back out of $\frac{3}{4}$-inch gas pipe, using five $\frac{3}{4}$ close return bends, and placed it in front of the heavy sectional cast-iron fire back in the stove, the water back being the full size of the fire back. Since putting it in the oven will not bake at all on the top and, also, bakes very much slower on the bottom. They use coal exclusively the year round and have exceedingly hot fires, yet the oven will not bake. The stove always baked well before the water back was put in. The reason I placed the water heating apparatus at the back was: 1. They wanted all the hot water they could get; 2, by putting it in front it would interfere with the drafts of the stove, and 3, I saw several different styles of ranges with water backs instead of fronts and thought if they baked all right this one should. I have heard that occasionally there is difficulty in baking in ranges so constructed.

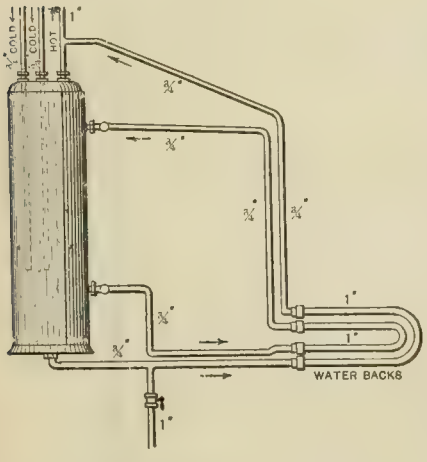
Note.—It is not unlikely our correspondent's difficulty is due to the fact that the water back takes out so much heat from the stove fire that not enough is left to bake suitably. He intimates that a great deal of hot water is used in this house, and it is needless to point out that if this is so, the great part of the heat of combustion of the coal is carried off by the water, and consequently does not go to the oven. We can make no suggestions except to

remove the water back or else increase the grate area. If any of our correspondents can offer better advice we will be glad to hear from them.

A Suggestion in Water Backs.

From A. H. F., *Lancaster, Pa.*—I am an apprentice and would like the readers of *The Metal Worker* to give me their opinion of this boiler and range connection, which I think would be a great advantage where the water back of a single range is not large enough, and where it is not desired to go to the expense of connecting two water backs to the boiler. The water front is made of 1-inch pipes. I think when put in as shown in the sketch they would not take up any more room than a cast water back and would give more hot water.

Note.—We have reproduced our correspondent's sketch, as it is an interesting modification of the ordinary water back, but we fail to see that it has any



A Suggestion in Water Backs.

special points of merit. The fact of the matter is, the heating power of the water back depends upon the surface it exposes to the fire, provided there be connections of suitable size between it and the range boiler. In the present instance a double coil, giving the surface of four lines of pipe and then connected by flow and returns of suitable capacity, would, we think, have fully as much heating power as the double arrangement shown.

Cold Air from Hall.

From WESTERN.—When locating a heating furnace, the expert furnaceman is supposed to devote a portion of his talent to the selection of a proper opening for the cold-air box. If the house is properly situated, the north or west side of the building is selected, and the cold-air box made equal in area to three-quarters of the total area of all the hot-air pipes. Under such favorable circumstances the furnace is supposed to operate in a proper manner and furnish the desired amount of hot air to each register. Does it do so? If the cold-air opening is on the north side of the house, during the prevalence of a north wind the opening will receive an unlimited supply of cold air, and if there is no one about the premises who has the interest of the furnace sufficiently at heart to close the opening by means of a slide or damper that should be provided, it is probable the cold air will be blown through the furnace before it becomes heated. Under such conditions the inmates may conclude that the name "hot air" as applied to the furnace is a delusion and a snare. The wind may change around and blow from the west. The result of this change will be that little if any air will enter the cold-air opening, regardless of how the slide or valve may be arranged, as the air will pass rapidly by the opening. The furnace may be filled with fuel and driven to its greatest capacity, yet the supply of hot air that comes out of the registers is not sufficient to warm the house. The inmates may wonder why, with a strong wind and a good fire, so little heat is given out.

The wind may change again and blow from the south. As this is supposed to be a warm wind, the people who inhabit the residence may fondly anticipate a change for the better in the furnace, but as the wind is from a direction opposite to the cold-air opening, not only may the air refuse to enter, but a suction may be formed sufficiently strong to draw air out of the cold-air opening. Each crack and crevice about windows and doors on the south side will then admit its share of air, which being colder (?) than the air in the house will have a tendency to flow along the floor until a register is reached, then down and out through the cold-air opening. Under such conditions the slide in cold-air box may be closed to prevent air from escaping, but there appears to be no way by which the air may be made to enter. When there is an east wind then the result is about the same as when the wind is from the west—it will blow directly across the cold-air opening and refuse to enter.

Some furnacemen endeavor to avoid the above difficulties by running a cold-air box from the hall to furnace, and perhaps connecting this box with the one from outside; then, in case the outside box fails to operate, the inner is used. This method may operate very well providing there is some one about the house who will devote sufficient time and attention to the management of the furnace. This much-to-be-desired person is seldom at hand, and in the majority of cases the furnace should be arranged in such a manner as to operate properly without an engineer or educated attendant.

There is another method in vogue among furnacemen by which they endeavor to overcome the difficulties encountered by the use of an outside cold-air supply. This consists in taking the air supply from the basement or cellar. This method is not to be commended, as it is difficult to get a proper air supply; besides, the dust and dirt from fuel and ashes are liable to be taken to the upper rooms by the air drawn through the furnace.

Those who desire to set a furnace in such a manner as to give satisfaction under all circumstances cannot do better than to take the cold-air supply from the hall or some convenient room. It is recommended that the duct leading from the hall to furnace should equal in capacity the total area of all the hot-air pipes. This will afford an abundant flow of air to the furnace, as all cold air from the floors will be drawn to the hall opening and then through the furnace, where it will be properly heated. An abundant supply of fresh air will be derived from the numerous cracks about doors and windows, and as this air will naturally flow in the direction of the cold-air opening in hall, it will become heated and returned to the rooms. In some cases it may be found expedient to take the air supply from some room besides the hall. In such a case this second inlet should be on the side opposite the hall inlet, and a partition placed between the two inside the furnace, and extending part way up the sides.

It has been the custom for years with some furnacemen to always use a cold-air box from outside in connection with a heating furnace, and such persons may not feel inclined to adopt a different method. They may be surprised to learn that for a number of years past it has been the practice with those who have done the most successful furnace work to dispense with the outside connection and take the air supply for furnace from a hall or suitable room. In numerous instances where furnaces have failed to operate properly when the air supply has been taken from outside, by changing the inlet so that the air would be conveyed from hall to furnace a great improvement has been observed in heating and a reduction made in the consumption of fuel.

Note.—From the standpoint of sufficient air supply our correspondent has presented a good argument, but we believe, nevertheless, that there are many furnacemen who will stick to the old plan in spite of its disadvantages. A frame house, especially of the rickety variety in the country, is well ventilated through the cracks about windows and doors, but a brick residence in the city is quite a different structure. Fresh air must be provided at any cost and it is fully as necessary as warmth.

Zinc Culinary Utensils.

From E. S., *Philadelphia.*—A visit to the cheap and other stores shows one many articles placed on sale that are coated with zinc. While ash pails and coal hods can be made of galvanized iron without injury to their usual contents, the same cannot be said of water buckets, dippers and other articles used in the kitchen. The highly decorated ice-water tanks may please the eye, but many of them are lined with zinc or galvanized iron. Zinc is acted upon by most waters, and may be detected in those which have been stored in galvanized-iron or zinc tanks. The corrosion is especially active if the coating is imperfect. Theodore G. Wormly, M.D., says: "As metallic zinc is more or less acted upon by certain articles of food, especially such as contain free organic acids or fatty matters, its use for culinary operations is not altogether free from danger. In an instance in which we were consulted, a family, consisting of eight persons, suffered with symptoms of zinc poisoning, occasioned by the use of apple-butter prepared with cider, which had been concentrated in a galvanized-iron pan. On chemical examination, the concentrated cider was found to contain 1.14 grains of zinc oxide in each fluid ounce."

Steamer for Bugs.

From SCHOOLFIELD, VASS & Co., *Danville, Va.*—In reply to "A. L. H.," of Pocahontas, Va., who inquires in the issue of the paper for June 24 concerning a steamer for bugs, would say that we are in a position to supply his needs.

State employment of convicts in road-making, which has been tried in New York State, is very generally approved and recommended for adoption as a step toward obtaining better country roads, and also because this occupation will not compete with free labor, as is the case with other prison industries.

TIN PLATES.

Plant of the Morewood Tin Plate Mfg. Company, Elizabethport, N. J.

Morewood is a name which has long been identified with the tin-plate industry of Wales, the founders of the well-known firm of E. Morewood & Co., now operating extensive mills at Llanelly and Swansea, having been among the pioneers of the manufacture in that country. The brands of tin and terne produced by the Morewoods are among the most widely known and appreciated plates in the market the world over. The firm's interests are now promising to become equally prominent in the New World. Promptly recognizing the fact that the making of tin plates was an industry inevitably bound to secure a permanent place among the manufactures of the United States, Messrs. Morewood wisely arranged for the establishment of branch works in this country.

To that end J. H. Rogers, the managing partner of the firm, crossed over to America a little more than a year ago, and as was announced in *The Metal Worker* at the time, secured property at Elizabethport, N. J., for the purpose of erecting there a tinning plant in which to coat black sheets rolled at the firm's Welsh mills. Subsequently a further and much more extensive investment was made in the purchase by the firm of a large tract of land in Gas City, Ind., with the view of erecting at that place a complete tin-plate manufacturing plant where the whole process of manufacture, from the breaking down of the raw material and its conversion into steel sheets for tinning, should be conducted. This plant, which is planned on a very extensive scale, is now in active process of erection, and the tinning department is ready to begin operations.

ELIZABETHPORT WORKS.

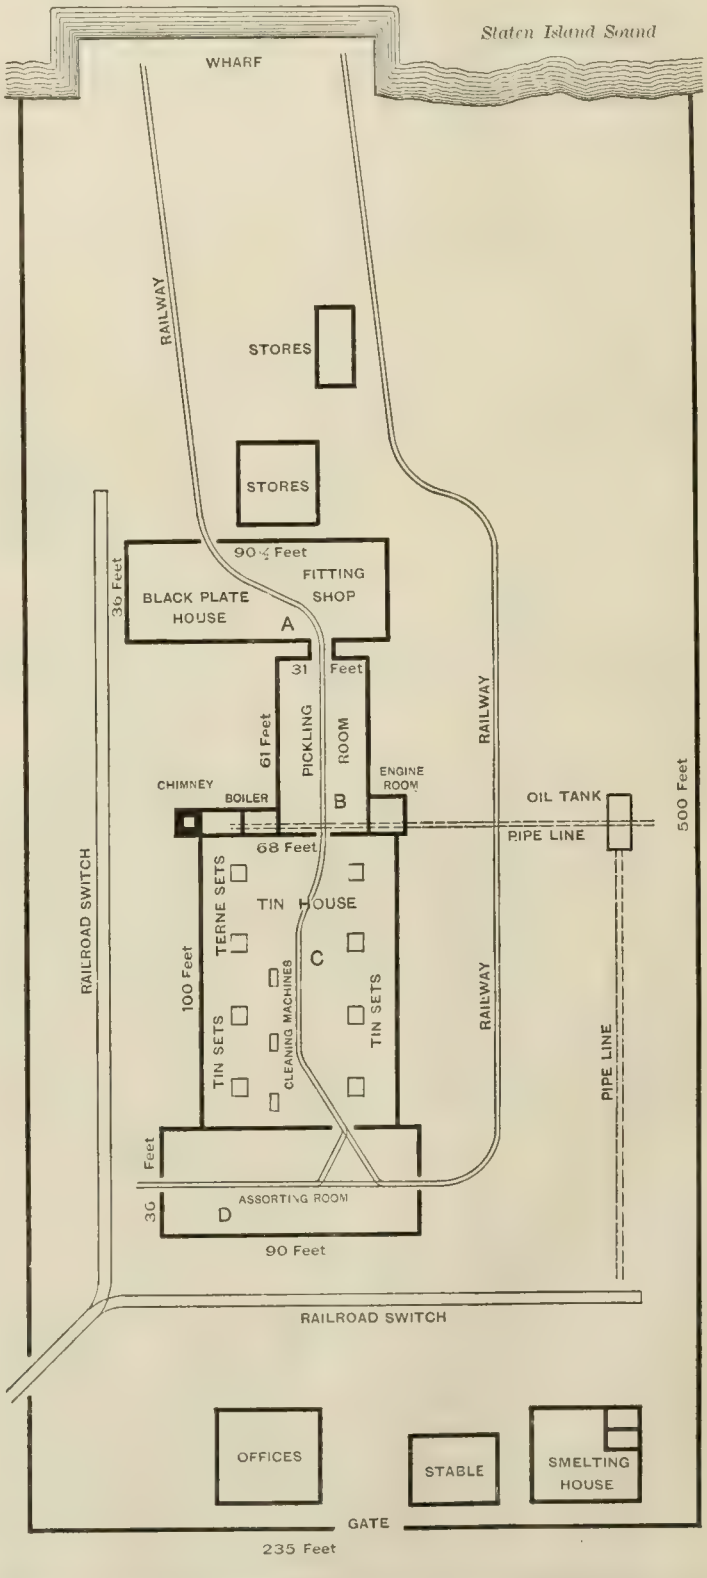
It is not, however, with these works that we purpose to deal at this time, but with the initial plant nearer home, which was first put into operation some eight months ago and which is to-day in full work, yielding a weekly output of 5000 boxes of tin and terne plates.

Although surpassed in size by a few similar establishments in the United States, the Elizabethport plant of the Morewood Tin Plate Mfg. Company, as a tinning plant pure and simple, is, in many respects, a model one. The company being, as we have stated, an affiliation of an old-established concern on the other side of the water, and having the advantages of a thorough knowledge and lengthened experience in the manufacture of tin plates on the best principles back of them, would naturally enter upon the business here under peculiarly advantageous conditions. Consequently, we find the works, as to plan and general arrangements, all that a tinning establishment should be.

The factory was built under the personal supervision of Mr. Rogers, in a remarkably short time, the first pots having been put into operation in little more than four months subsequent to the purchase of the ground.

LOCATION AND SHIPPING FACILITIES.

The location of the buildings is excellent, affording the most favorable facilities for shipping by land and water. They stand in a 3-acre lot at the corner of Bay Way and Front street, Elizabethport, the rear of the works extending to the shore of Staten Island Sound, where a clear water frontage of 235 feet has been secured. Side tracks, connecting with the line of the Central Railroad of New Jersey, enter the premises, as shown in the plan view



Plan of Works of Morewood Tin Plate Mfg. Company, Elizabethport, N. J.

given herewith, and give the necessary means for shipments to the West. The bulk of the product is, however, transported by water, and the raw material and supplies are received by the same channel, the company's own lighters, fitted with cranes and all appliances, being used for this purpose. A wharf has been built on the water face, where loading and unloading is done, the material being run to and from the shops in hand cars over a double track, which traverses the entire round of the establishment.

BUILDINGS AND THEIR CONTENTS.

On the accompanying plan will be found the general disposition of the works, with the arrangement of the various buildings, &c. These are entirely fire proof, being formed of a structural iron frame work, covered with galvanized corrugated sheets. The stacks are of brick, and every precaution has been taken to obviate fire risks in all parts of the plant. The structures are placed in a rectangular plot, surrounded on three sides by a high wooden fence and bounded on the fourth by the water. Ample space has been left for further extensions of plant, as time and trade may render desirable. Nothing is cramped, yet all is compactly arranged.

The raw material, on being landed, is transferred to one of the stores marked on the plan. In the case of black plates, which require the largest amount of space and the most care, storage room is found in the first of the main buildings. Other storehouses for pig tin, palm oil, bran, packing boxes and the various requisites, being located between the shops and the wharf. The rest of the building (marked A on the plan) is used as a fitting shop where the necessary repairs and machine work are carried out. The adjoining building, B, is the pickling room, which holds a Hutchins' patent pickling machine having a capacity of about 1000 boxes a day. The apparatus, which is worked by a stationary engine, operates three cradles of yellow metal attached to arms revolving round a piston working in a vertical cylinder. Large pickling and swilling tanks are placed on either side. The cradles, when immersed in the vats, are given a simultaneous up-and-down and side motion, so as to thoroughly wash the plates, the frames of the cradles resting on the edge of the vats, being fitted with runners which work in a groove. Tanks of water in the same room retain the pickled sheets until required for tinning.

The black sheets at present used are those which have been rolled at Messrs. Morewood's mills in Wales. They are black pickled, cold rolled and squared before being sent to this country. Consequently the only operations undertaken at the Elizabethport works are the second, or white, pickling, and coating.

Adjoining the pickling room on one side is the engine house, where a small oil engine is placed. It should be mentioned that oil fuel is used exclusively in the works. It is operated on the Aërated Fuel Company's system, and is found to be economical, effective and cleanly. The boiler is housed on the opposite side of the pickling room. A large chimney next to it carries off the vapors from the entire works.

THE TINHOUSE.

Opening from the pickling room is the tinhouse, an airy, light and well ventilated building, 100 feet long by 68 feet wide, holding eight of the Morewood tinning machines, now becoming familiarly known to American tinners, and, therefore, requiring no detailed description. Six six-roll pots, each having a daily capacity of 100 boxes, are devoted to the production of bright plates. The remaining two pots are of larger dimensions and capacity, and somewhat different in arrangement, being automatic in their action. These machines are used for coating terne plates and have combined a weekly capacity of 2000 boxes. Each pot holds about 15 tons of molten metal. The black sheets are fed into a flux box at one end of the machine, pass down into the metal pot and through a heavy pair of rolls fitted with finger guides, which push them up through a grease pot at the other end, when they are seized by a second and a third pair of rolls and pushed upward, almost all the grease being removed in passage. The plates, on emerging, require only a light rub over with a cloth.

Alongside each of the six bright tin pots is a Morewood cleaning machine, into which the coated plates are fed as soon as tinned. These remove the grease, and the tin plates are then transferred to a line of three Richmond patent dusting machines, placed in the center of the room, where they pass through rolls of india rubber and sheepskin, and are given the final polish. From the tinhouse the plates are taken to the assorting room D, where they undergo a scrupulously careful examination and sorting, all not found to be up to the standard being rejected and sold as "wasters." Stamping and boxing follow, and the finished goods are placed on trucks ready for shipment. No stock is retained at Elizabethport. Each day's product is immediately shipped, either by lighters to the company's selling agents at New York, or by water or rail to other points, in response to orders.

OTHER FEATURES.

A couple of large smelting pots are located in a separate building, having its own smokestack. Here the "scruff" collected from the pots is brought weekly and smelted, about 60 per cent. of pure tin being recovered from it.

The railroad siding, which enters the premises on the left, bifurcates inside the fence, one branch running toward the sea face as far as the end of the main buildings. The other track crosses between the shops and the outer buildings. This is used for the oil-tank cars, which discharge into pipes communicating with the storage tank, shown on the plan. The latter again communicates by means of feed pipes with the engine and boiler rooms and other parts of the works. Offices, stables, &c., as shown, make up the balance of the establishment.

The grades of tin and terne plates produced are identical with those made at Messrs. Morewoods' Welsh works. So far the product has been more or less confined to B. V. bright coke plates and P. T. L. ternes, but all the other brands of tin and terne made by the firm at Swansea and Llanelly can be made here. These include the well-known names Vivian Y. & B., Grange, Llannon (three crowns), Pentre, M. & J., Gloster and Park. The B. V. coke plates, of which 3000 boxes are now being turned out weekly at Elizabethport, are in great demand for canners' use. They are made of best Siemens steel and are highly finished.

All the tinning sets have been maintained in full operation ever since the first opening of the works in October last. Two hundred hands are employed, working in night and day shifts alternately, and we understand that it is all the company can do to keep abreast of their orders, although running to full capacity of the works.

J. A. Rogers, who is at present in Europe, is president of the Morewood Tin Plate Mfg. Company, and the works are under the immediate direction of the vice-president, H. Coulson Bond, who is assisted in the management by C. M. Stewart, both having had practical experience of the business at the home works in Wales.

SCRAP.

IMPORTS OF TIN and terne plates at San Francisco last year amounted to 374,426 boxes.

THE MELYN TIN PLATE WORKS, Neath, Wales, were partially destroyed by fire on June 10.

BELOW will be found the imports of tin and taggers metals at the port of New York, according to the latest returns:

	Week ending June 30, 1893.		Week ending June 24, 1893.		26 weeks of 1893.
	Quantity.	Value.	Quantity.	Value.	Quantity.
Tin, slabs	852,047	$185,186	649,957	$127,165	29,939,971 pounds.
Tin, boxes	64,293	205,725	43,512	147,040	1,103,824 boxes.
Taggers metal, boxes	4,895	16,785	4,210	13,452	

A VERY APPRECIABLE FALLING OFF is reported from Wales in the American demand for roofing ternes. Business in that line is stated to be unusually light this year.

JOHN BROMILOW, an Englishman of experience as superintendent of mills making black sheets for tin plate and of open-hearth steel plants, is stopping at the Commercial Hotel, Braddock, Pa., looking up this industry with a view of becoming interested.

F. R. SLAUSON, representing the interests of the Piqua, Ohio, tin-plate manufacturers, is now in charge of the World's Fair tin plate exhibit, which is daily visited by many interested inquirers, and if souvenirs were given out a small mill would be kept well occupied.

FOR THREE MONTHS ending March 31 the output of the Irondale Rolling Mill & Tin Plate Works, Wallace, Banfield & Co., Limited, at Irondale, Ohio, amounted to 2,088,221 pounds of black sheets. Of this product 1,121,381 pounds were tinned, 234,194 pounds were made into terne plate and 732,646 pounds were sold in the open market to other manufacturers of tin plates for tinning purposes. The plant of this firm is being operated to its utmost capacity, and they are entirely sold up on tin and terne plates and black sheets until September 1 next.

The late landslip in Norway extended for 7 miles, carrying away 40 farms and causing the death of 113 persons and many hundreds of cattle.

PLUMBING and GAS FITTING.

Examination of Plumbers.

From Y. M.—Is it necessary to go before the Board of Examining Plumbers and take out a diploma to carry on the plumbing business in New York, if I am not doing any work that requires a permit, such as opening streets or repairing water mains?

Answer.—The fifth section of the bill known as Chapter 620 of the laws of New York State, 1892, clearly states that "any plumber designing or intending to conduct the business of a plumber or of plumbing" must comply with the provisions requiring examination and license. The law does not, however, apply to a journeyman plumber who is hired by the owner or some one having an interest to do certain work. It is only when he undertakes to do a piece of work which he cannot complete without employing plumbers that the law comes into effect. The journeyman plumber doing such indoor work as our correspondent refers to must comply with the old and still existing rule of registering his name, &c., as journeyman, in the books of the Health Department, in order to be able to recover in court.

Sanitation *

BY JAMES H. O'NEILL.

a. Should Sanitation be Fostered by Legislation?

b. Should Legislation Precede Education?

c. The Extent of Municipal or State Authority in Sanitary Matters.

I do not propose to treat the subject of sanitation in an exhaustive manner; it will suffice to draw attention to a few prominent points and their sequences. To begin with:

SHOULD SANITATION BE FOSTERED BY LEGISLATION?

At this time of day it seems almost unnecessary to reply, but, for form's sake, let me give an object lesson. London, like many other Old World cities, at the beginning of the present century had a death rate exceeding its birth rate; hence its population was kept up only by fresh blood from the rural districts. Being a tidal city, the river Thames, on which it is situate, alternately, twice a day, filled its urban bed and left exposed to the rays of the sun a mass of black mud, hateful to the eye and offensive to the nose, which was the product of the city sewers of which the river was the terminus; hence the terrible death rate.

There are two theories of government: One—that of France, Russia and Switzerland—the paternal system, where the Government is understood to attend to everything; the other, of which, until recently, England was the best example, where the Governmental interference is limited and the "go-as-you-please" principle is asserted.

Public opinion on the tariff and labor questions in this country has divided the voters into bodies representing these ideals. But whatever divisions there may be on certain subjects, all are agreed that the province of legislation includes the preservation of life and property; also, that the State or nation, being, in its ultimate definition, a society for necessary co-operative purposes, is bound to act where individual effort would be impossible. So it was that London came to provide a colossal and flushable common sewer, constructed on ground taken from the river; its upper surface earth-covered and planted with flowers and shrubs forms a gay parade. The river, now clear and bright, no longer offends the eye and the nostrils and moves more quickly within its narrow banks. Best of all, the death rate was lowered to 18 per 1000 per annum—a reduction of about 50 per cent., if I remember rightly. The population of inner and outer London is now 6,000,000, but on a 3,000,000 basis the annual saving to humanity would be 54,000 lives per year, or 3,250,000 in 60 years.

Without legislation individual effort would be utterly powerless in this and all instances. No costly defensive armies ever produced such valuable results.

After a time, London found by gradual increase in the death rate that individual connections with the public sewer were often faulty. In London, Glasgow, Edinburgh and elsewhere voluntary Sanitary Mutual Protective Associations sprung up, which provided, among other things, for periodical investigation of all plumbing work on the part of the members. The results were insufficient and municipal legislation followed.

If the city sewers are as nearly perfect as possible, much still remains; leakage of house drainage poisoning the soil around, and subsequently the air, is the fruitful origin of multitudes of deaths from malaria, typhoid fever, diphtheria, &c., besides the cost to individual survivors, and hence to the community, of long sickness and absence from employment.

An instance of the pervasive nature of malaria comes from Switzerland. A village there, situated on a flat-topped foot hill, derived part of its water supply from a near-by pond into which the village drainage flowed. The pond received a small stream, but had no visible outlet. A malignant type of typhoid fever broke out, and the paternal Government authorities at once isolated the village by placing troops around. To their undisguised surprise typhoid fever soon after broke out in a village situated in a valley at the foot of the hill on which the first-named village was situated, and whose water supply was obtained for the most part from a stream bursting from the hillside, and which people suspected had subterraneous connections with the pond above referred to. To test the matter the Government experts nearly emptied the pond, cleaned out its mud, then poured into it large quantities of the finest flour. The closest microscopic investigations of the hillside stream showed no sign of the flour or its discoloration. In a second experiment they poured large quantities of salt into the pond. Now the hillside stream becomes a saline one. It was now clearly evident that typhoid fever could pass through a clay filter which afforded no passage for the finest particles of flour. This is a simple but complete object lesson of the perils of infiltration.

Unfortunately we have, within our own country and our own knowledge, in the multitudes of deaths from typhoid fever or drain fever, malaria and diphtheria, sad lessons enough. I remember a young physician, prospering in his profession, who moved to a larger and finer house in rather a low-lying district. He had three fine children; after his removal they died, one by one, in rapid succession; not until the last dread messenger had called did he discover there was an ill-trapped sewer on the premises.

Plainly, legislation is necessary: 1, To prevent the sacrifice of human life; 2, to prevent the financial losses consequent upon long-continued sickness and deaths; 3, to preserve us from quacks and incapable persons.

SHOULD LEGISLATION PRECEDE EDUCATION?

I think it must—we cannot all be generals or soldiers, it requires military training; we cannot all be M.D.'s—that would require education at Ann Arbor, Bellevue or other university; we cannot all be military, civil, or sanitary engineers, neither can we all be skilled plumbers. Legislation should, recognizing popular ignorance, give in all its preambles a brief statement of the salient points we have noted, and as the State calls to its aid in times of war and epidemics the soldier and the doctor, and in times of panic the financier, so the law makers should co-operate with the sanitarian, and the recognized master plumber with the experts, so to say, in framing proper laws and regulations on these matters, including the careful examination of candidates for licenses as master plumbers.

THE EXTENT OF STATE OR MUNICIPAL AUTHORITY IN SANITARY MATTERS.

As to this proposition I should say the authority of the State is that of the people of the State, and has no limit except where United States forts, or the like, may be within its bounds, and sometimes not even then. Another limit is where power has been delegated to the municipality, which, also, is supreme within the range of its power so acquired. The National Association of Master Plumbers should be, and is, able to present to all governments—State and municipal—a full scheme or outline of the necessary elements of all sanitary legislation, and the incidental rules and regulations consequent thereupon.

It is only thus, by a co-operation of power and skill of the intelligent legislator and the skilled master plumber—that the health and welfare of the whole population can be conserved.

The undersigned respectfully suggests to the National Association the propriety of preparing forms of necessary legislation, State and municipal, suited to all parts of the country, which might be made the work of a well-selected special committee.

* Paper presented at the Milwaukee Convention of the National Association of Master Plumbers, June 13-16, 1893.

TRAPS AND VENTS.

B. F. McFarland, Indianapolis, Ind., manufacturer of the American bathtub system, finds a growing demand for his goods. A galvanized tank is located convenient to a heavy zinc bathtub, and a pump is connected with them to draw water from a well or cistern to the tank, where a gas burner heats the water. By opening a cock in the bottom of the tank the tub is supplied. In the country and among farm houses it has found much favor, as gasoline can be used where there is no gas supply.

The Milwaukee Brass Company of Milwaukee, Wis., are getting up patterns and tools for the manufacture of the Fuller system of faucets, &c.

Samuel S. Hibbs is untiring in his search for customers for bath boilers, tanks, stacks and heavy sheet-iron work for the house of E. A. Hibbs at Philadelphia. At present the shop is running at full blast.

The Supervising and Examining Board of Plumbers of Troy, N. Y., have chosen William Ferguson as president and Joseph C. Ryan as clerk.

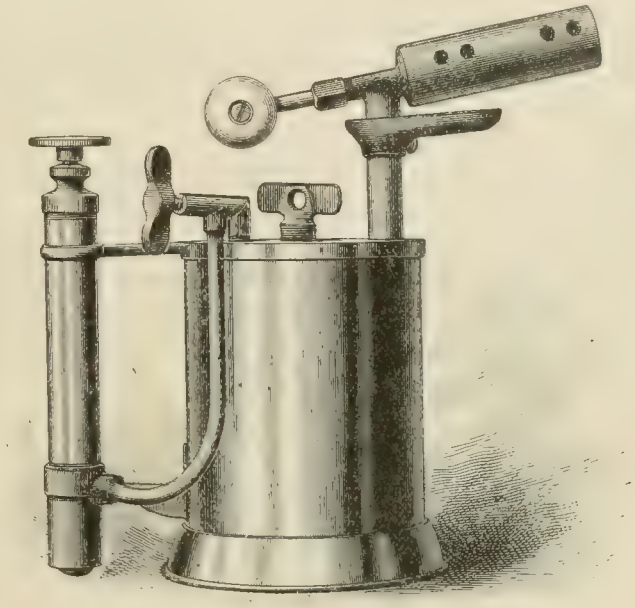
The New Jersey Lamp & Bronze Works, New Brunswick, N. J., have published a very elaborate catalogue of electric and gas fixtures, which they are sending to the plumbing and house furnishing trades on request by letter. The publication is artistically bound in chocolate-colored covers with gilt design on the front. It is oblong in shape, measures 6 x 9½ inches, and the leaves are fastened at the top by a blue silk cord. The printing is entirely on one side of the page, and is done in differently tinted inks, with very pleasing effect. The first few pages of the catalogue give particulars concerning styles of fixtures and drawings, mentioning the kind of metal work the firm make to order, then continues with information concerning colors and finishes, glassware, extra lengthening, shipment of goods and a statement of the particulars requested in ordering goods. Accompanying the different illustrations are their catalogue numbers, together with names, code words, size and other important information. The pages have a very pleasing effect, for the text is brief, and the cuts in colored ink show on the fine paper with beautiful effect, some of the earlier bronze figures being especially attractive. At the close of the pamphlet reference is made to miscellaneous electrical supplies. Altogether the volume is gotten up in a very handsome fashion, and will no doubt be much appreciated by the trade. It is worthy of note that this elaborate work was published by the private printing department of the New Jersey Lamp & Bronze Works.

Henry R. Worthington are distributing serviceable little souvenirs respecting their exhibit at the World's Fair. One of the pamphlets is a map giving a plan of the World's Fair, the location of the Worthington exhibits being noted, while the accompanying text indicates what they are. On the back of the sheet is a plan of Chicago and the World's Fair, showing the means of communication and the location of the different prominent buildings, including the branch office of Henry R. Worthington. Another pamphlet gives a description of the Worthington pumps, together with a smaller map of the fair grounds.

The cultivation of flax in the United States is recommended as a promising industry by our commercial agent at Dunfermline, Scotland.

Empire Blow Pipe and Paint Burner.

Tinners' Machinery & Supply Company, 9 Cliff street, New York, are introducing an improved blow pipe and paint burner, as here shown, which will be known as the Empire. It has a heavy rolled brass cylinder 5 x 4 inches, capable of withstanding high pressure. A pump is placed in the handle and air is introduced into the reservoir by means of a curved pipe to which a valve operated by a thumb screw is attached. In the top is a cast-iron plug to close the opening through which gasoline is poured into the cylinder. The tank should never contain more than two-thirds or three-quarters of its capacity.

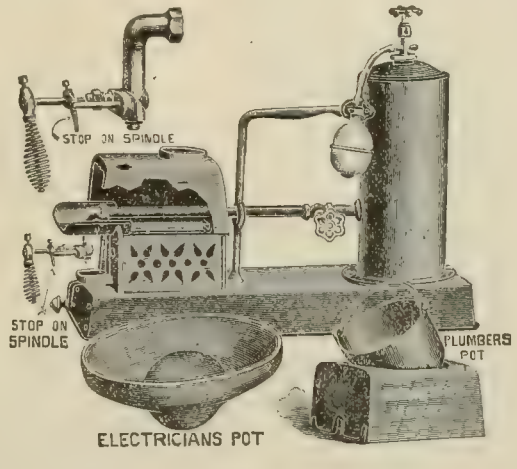


Empire Blow Pipe and Paint Burner.

Fastened by a set screw to the standard of the burner is a cast-iron drip cup. During the process of charging the needle screw in the burner should be made tight to permit the accumulation of air. When in use the needle screw is opened enough to allow gasoline to drip into the cup until full, when it is closed again and the oil lighted. This cup holds a sufficient quantity of oil to vaporize the gasoline, so that when the needle screw is opened a flame is produced, the intensity of which can be regulated. All the parts are interchangeable.

Improved Burgess Soldering Furnace.

The accompanying illustration shows the appearance of an improved form of Gem No. 3 furnace, made by the Burgess Soldering Furnace Company, Columbus, Ohio. The improvement is in the regulating valves of the furnace and is applied to all the Gem furnaces Nos. 3, 4, 5, and 6. The feature of the improvement is the stop on the spindle, its object being to prevent the operator from turning the Alaska handle two or three turns. Heretofore the old valves had no stop of this sort and by turning the handle two or three times the threads on the needle rod would destroy the asbestos packing in the stuffing nut and cause it to leak. With the stop on the spindle the operator can only turn the handle one-half revolution, which will allow a full flow of gas and prevent the threads of the needle rod from destroying the packing and thus avoid leakages. The stop is adjustable, and we understand that those who handle the furnaces say it is a very decided improvement, as it simplifies the operation so that inexperienced persons can run it easily.



Improved Burgess Soldering Furnace.

Electric traction is likely to get a foothold in the streets of San Francisco.

THE TIN SHOP.

Pattern for Ship's Ventilator.

From W. S. W., *Michigan City, Ind.* —Inclosed find the elevation, section and pattern of a ship's ventilator. I tried to obtain the pattern by working it the same as Fig. 367 in *The Metal Worker* Pattern Book, but it will not come out right. The sections will not fit together. I would like to be informed where I made my mistake.

Answer.—Figs. 366 and 367 in *The Metal Worker* Pattern Book refer to a conical flange to fit around a pipe and against a roof of one inclination. In this example the part of cone through which the pipe is to pass is cut at right angles to its axis. The part of cone that is to fit against the roof is cut oblique to its axis, and the shape produced by this cut is an ellipse, as shown in plan, Fig. 366.

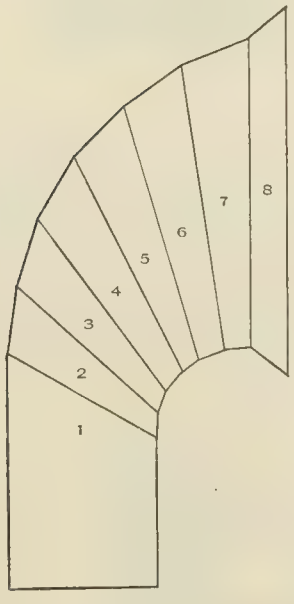


Fig. 1.—Elevation of Article for which Patterns are Required.

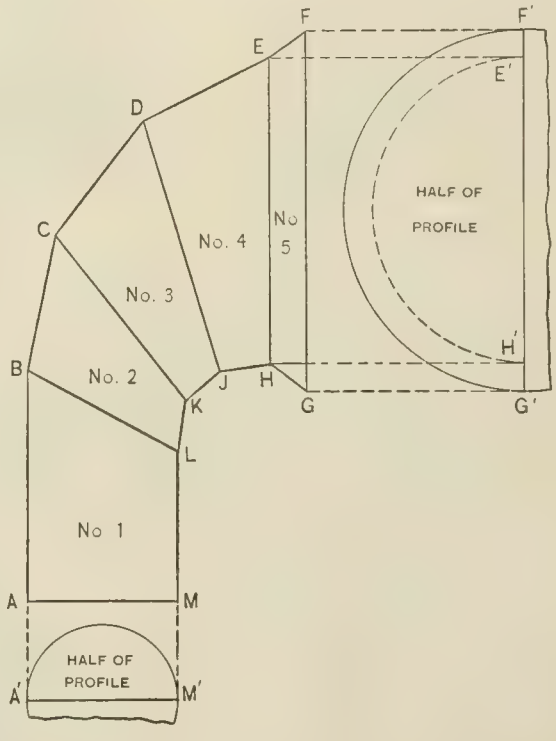

Fig. 2.—Elevation of Article Used in Following Illustrations.

PATTERN FOR SHIP'S VENTILATOR.

In Fig. 1 is shown the elevation of article for which the patterns are desired. For convenience of illustration the elevation of article has been changed, as shown in Fig. 2. In this figure, A B L M is supposed to represent a cylinder cut by the line B L. The shape produced by cutting a cylinder oblique to its axis is an ellipse. Section Nos. 2, 3, 4 and 5 are supposed to be obtained from cones, as indicated by the method used by the correspondent, shown in Fig. 4. Three of these cones are shown in Fig. 3. Section No. 5*a*, as indicated by E*a* F*a* G*a* H*a*, is the frustum of a cone of which R*a* is the apex. Section No. 4*a*, indicated by D*a* E*a* H*a* J*a*, is a section of the cone E*a* N*a* Q*a*.

The cut E*a* H*a*, being oblique to the axis of the cone, will be an ellipse, while the cut D*a* J*a*, being at right angles to the axis, will be a circle. Section No. 3*a* is derived from the cone D*a* O*a* P*a*. The cuts D*a* J*a* and C*a* K*a* are each oblique to the axis of the cone D*a* O*a* P*a*, consequently each cut will be an ellipse. The same can be said of No. 2*a*. Want of space prevents the showing of this cone. We can now see why the various sections will not fit together, as the cut D*a* J*a* of No. 3*a* is an ellipse, while the cut D*a* J*a* of No. 4*a* is a circle. Also, the cut E*a* H*a* of No. 4*a* is an ellipse, while the cut E*a* H*a* of No. 5*a* is a circle.

The method pursued by our correspondent for obtaining the pattern of section No. 4*a* is shown in Fig. 4. In this figure E*b* N*b* Q*b* represents the cone, which is cut as indicated by the lines E*b* H*b* and D*b* J*b*. The method employed by our correspondent in cutting the pattern of the frustum is that commonly used in similar problems in *The Metal Worker* Pattern Book, and in itself considered is correct. The error of the correspondent probably arises through the assumption that sections of different cones cut by oblique lines will fit together. In this connection it should be borne in mind that each segment must be developed from the section of the cone immediately preceding and with which it connects.

In Fig. 5, let E*d* N*d* J*d* D*d* represent the frustum of a cone of which E*d* H*d* J*d* D*d* is a section. To obtain the length of the minor axis of ellipse formed by the cutting plane E*d* H*d* proceed as follows: Bisect E*d* H*d* in *x*, and through *x* draw *y z* parallel to the base E*d* N*d*. As *p o* is the axis, from *i* as center, and with *y i* as radius, describe the semicircle *y w z*. From the point *x* and parallel with *o p* draw *x w*, extending it until it cuts the semicircle *y w z*. Then *x w* is the semi minor axis of the ellipse. In the ellipse below, *u v* is equal to E*d* H*d*; *p t* and *p s* are equal to *x w*. The ellipse *u t v s* can be described in any convenient manner, and is the shape produced by cutting

the frustum of the cone E*d* N*d* J*d* D*d* by the line of cutting plane E*d* H*d*. Referring to Fig. 3, the shape produced by cutting the cone E*a* N*a* Q*a* by the oblique plane E*a* H*a* is shown in Fig. 5 by the ellipse *u t v s*. Also, the shape produced by cutting the cone F*a* G*a* R*a* in Fig. 3 by the plane E*a* H*a* is shown in Fig. 5 by the circle *u r v q*. It must be evident that the sections 4*a* and 5*a* in Fig. 3 could not be put together without bending one or the other out of shape.

In Fig. 6 the shape produced by the cutting plane D*e* J*e* is shown by *l o m n*.

In Fig. 7 the various shapes are contrasted. The section No. 4*f* is the same as No. 4*a* in Fig. 3. The half shape of cut on line E*f* H*f* is indicated by E*f t* H*f*. The shape it is supposed to join on section 5*a* is indicated by E*f r* H*f*. Also, the shape of cut indicated by D*f* J*f* is shown by D*f k* J*f*. The shape of cut produced by the line D*a* J*a* for the section No. 3*a*, in Fig. 3, is indicated by D*f n* J*f*. That sections of various cones will not go together as desired must be evident from an inspection of the previous engravings.

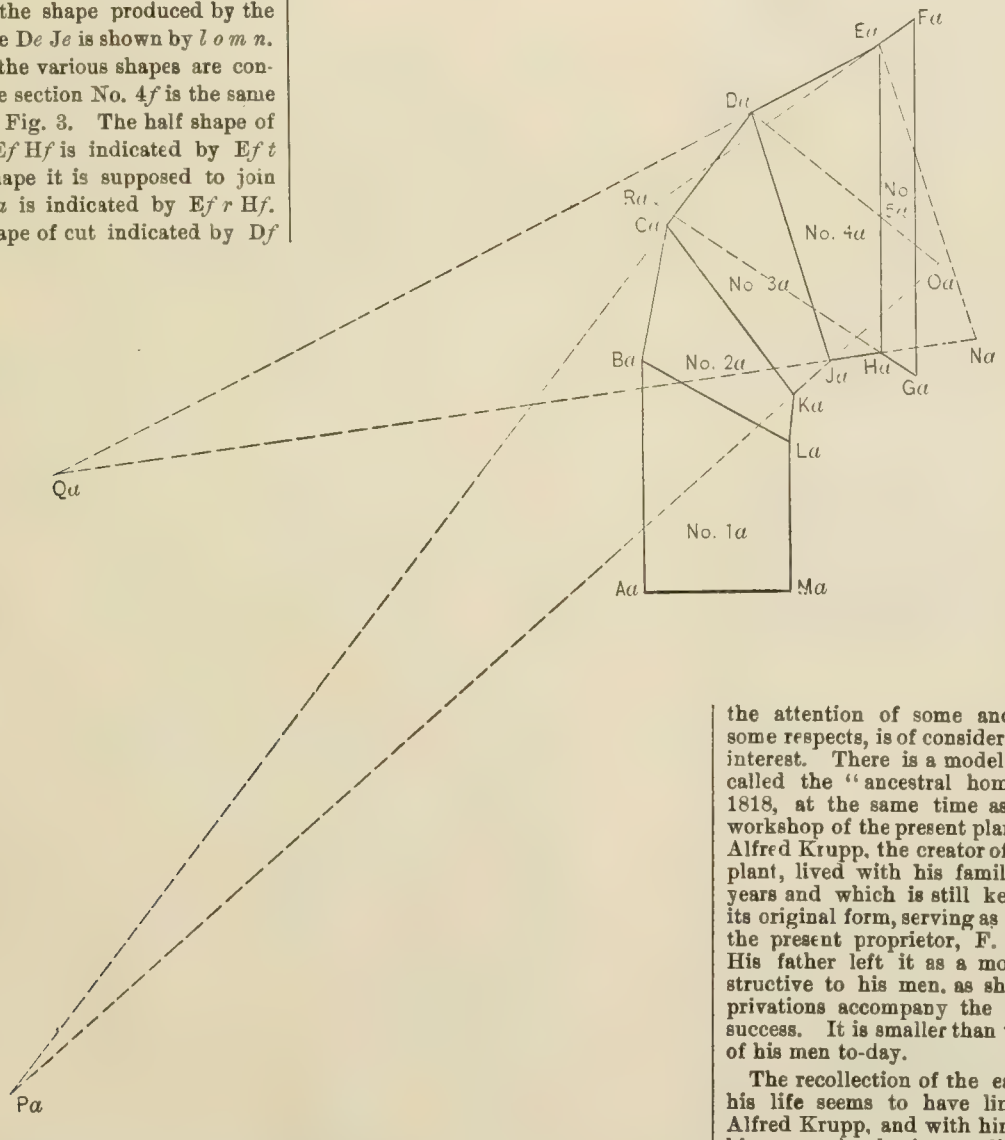

Fig. 3.—Three Cones from which Sections are Derived.

PATTERN FOR SHIP'S VENTILATOR.

Referring to Fig, 2, section No. 1 is a cylinder, as indicated by the half profile A′ M′, which is cut by the plane B L. The shape of this cut would be an ellipse whose major axis would be equal to B L, and the minor axis to A M, the diameter of the cylinder. As the shape of section No. 5 on lines E H and G F, as indicated by the half profiles F′ G′ and E′ H′, is a circle, the part of section No. 4 where it joins No. 5 should also be a circle. We can then consider that the line E H is to represent a circle, and also that the line B L represents an ellipse. Thus the shape on two of the miter lines is established. To obtain the patterns for sections Nos. 2, 3 and 4, the shapes on miter lines C K and D J can be modified as desired so as to conform to the two established shapes. It must be evident that the mistake made by our correspondent was in assuming that sections of various cones, cut by oblique lines would go together as indicated by the elevation.

George Wheeler, for upward of 40 years connected with the hardware trade in New York, died June 19 at his home in Brooklyn, aged 61 years. He was born in England and came to this country when a lad with his parents. At different times he was connected with the Peck Smith Mfg. Company, now known as the Peck, Stow & Wilcox Company, Landers, Frary & Clark, Scovill Mfg. Company, and for the last ten years represented John Chatillon & Sons on the road, being in their employ at the time of his decease.

Krupp and His Workmen.

The great majority of Americans have learned to couple the name of Krupp with the manufacture of great guns, while a few know of and appreciate the achievements of the firm in the production of various forms of merchant steel plates and track material. The exhibit at the fair will open the eyes of many to the high character and magnitude of the work done. Yet there is one part of the exhibit which has not escaped the attention of some and which, in some respects, is of considerable general interest. There is a model of what is called the "ancestral home," built in 1818, at the same time as the oldest workshop of the present plant, in which Alfred Krupp, the creator of the present plant, lived with his family for many years and which is still kept intact in its original form, serving as the office of the present proprietor, F. A. Krupp. His father left it as a monument instructive to his men, as showing what privations accompany the struggle for success. It is smaller than the quarters of his men to-day.

The recollection of the early days of his life seems to have lingered with Alfred Krupp, and with him and with his son a wise business policy has stimulated efforts to make the surroundings of their men as satisfactory as possible. There is an assumption of parental authority in a good many of them, which would probably defeat its good objects in this country by arousing, possibly, unreasonable opposition, in the face of the fact that it is coupled often with princely generosity. But, withal, the arrangements rest on a strictly business-like foundation, and are not tainted by any sickly sentimentality, nor is there about them any flavor of lordly patronage productive of constant irritation and disgust. We are indebted to A. Lauter, one of the representatives of the firm, for volumes which describe in detail the arrangements for the welfare of the firm, which are in charge of a special branch of the administration.

Founded in 1810, it was really not until the forties that the undertaking was of any consequence whatever. In 1832 ten workmen were employed. In

1843 the number of men employed by Krupp who were residents of Essen had risen to 99, and only went beyond 1000 in 1858 and 2000 in 1861, the population of the whole town being 20,766. In 1871 the town had a population of 51,840, of whom 8810 were Krupp workmen, the whole number of dwellings being 3322. While in 1840 an average of only 7.53 persons occupied a house, there were 15.5 souls under one roof on an average in 1891. The construction of company houses had begun at Alt-Westend in 1863, but it was not until 1871 that the problem became a matter for serious consideration. The rapid development of the plant had attracted a large working population with which local building activity had not kept pace. Uncomfortable quarters drove the men to groggeries and beer houses, which increased in number amazingly. The fact that the population has been drawn from very different sources led to frequent trouble, and demagogues began their work of creating unrest.

Heroic measures were called for, and in the years 1871 to 1873 not less than 2358 family dwellings were built. A number of considerations, probably valid at that time, but hardly so now, put the introduction of the cottage plan out of the question. Real estate was high, and it was deemed necessary that the men should not be living at too great a walking distance from the works. Then the scattering of the homes over too large an area would make the water supply too expensive. A number of colonies were established, each of them having its schools, churches, company stores, markets and parks. The following statement shows the number of houses and the number of dwellings, or suites of rooms, which they contain:

	Houses.	Suites of rooms
Alt-Westend, 1863	8	144
New Westend, 1871	18	108
Nordhof, 1871	..	162
Baumhof, 1871	41	154
Schederhof, 1872	82	492
Schederhof Barracks, 1872	70	280
Cronenberg, 1872-74	221	1,356

The last named may be taken as typical of the arrangements. The colony contains the following:

97 houses, each 6 suites of 2 rooms.
31 houses, each six suites, three of 2 rooms and 3 of 4 rooms.
80 houses, each 6 suites of 3 rooms.
2 houses, each 3 suites of 5 rooms.
2 houses, each 6 suites of 3 rooms.
3 houses, each 6 suites of 4 rooms.
6 double houses, 18 suites of 2 rooms each.
6 double houses, 36 suites of 3 rooms.
6 double houses, 18 suites of 4 rooms.

The company houses are rented only to employees, preference being given to those having long service with the firm. Boarders are allowed only when it is deemed advisable, the total number being only 256. The annual rental is $15 to $22.50 for two-room suites in the barracks, $22.50 to $27.50 in other two-room dwellings, $30 to $40.50 in three-room, $45 to $50 in four-room and $52.50 to $82.50 per annum in five-room suites, deducted semi-monthly from wages.

On July 1, 1892, the firm had 25,200 employees, whose families of 62,700 carried the total population up to 87,900. Of these there lived in their own houses 15,300; in houses owned by Krupp, 25,800; and in outside houses, 46,800.

The outlay for 3659 suites of rooms at the Essen plant, and the income, were as follows:

	Marks.	Marks.
Cost of houses	11,042,451	
Real estate	1,213,624	
Total cost	12,256,075	
Income:		
Rents		484,675
Deduct repairs	112,678	
Deduct gas, water, repairs, &c.	67,650	
Deduct taxes and insurance	48,000	
Expenses		228,328
Balance		256,347

On a capital outlay of roughly $3,000,000 was realized $62,575, or about 2.1 per cent., which is a low rate of interest even for the Continent. The figures are a little better for the 523 suites of rooms at outside works and mines. The cost was 1,742,335 marks, which yielded a gross rental of 67,045 marks, and a net revenue of 44,955 marks, or 2.58 per cent. on the investment.

In 1889 F. A. Krupp went a step further and set aside the sum of 500,000 marks as a loan fund, from which workmen or employees may borrow at 3 per cent. interest to build their own homes. The yearly income of the applicant must be less than 3000 marks, he must show three years' irreproachable service, must have served his time in the army, and must make a first payment of at least 300 marks out of his own means. The money borrowed must be repaid in semi-monthly installments so that the mortgage is extinguished in 25 years. The loan may be called at once if the property is transferred to another party, or if the borrower has been dismissed or leaves the employ of the firm voluntarily within the first ten years. Thus far 75 houses ranging in value from 1000 to 13,000 marks have been built under this arrangement.

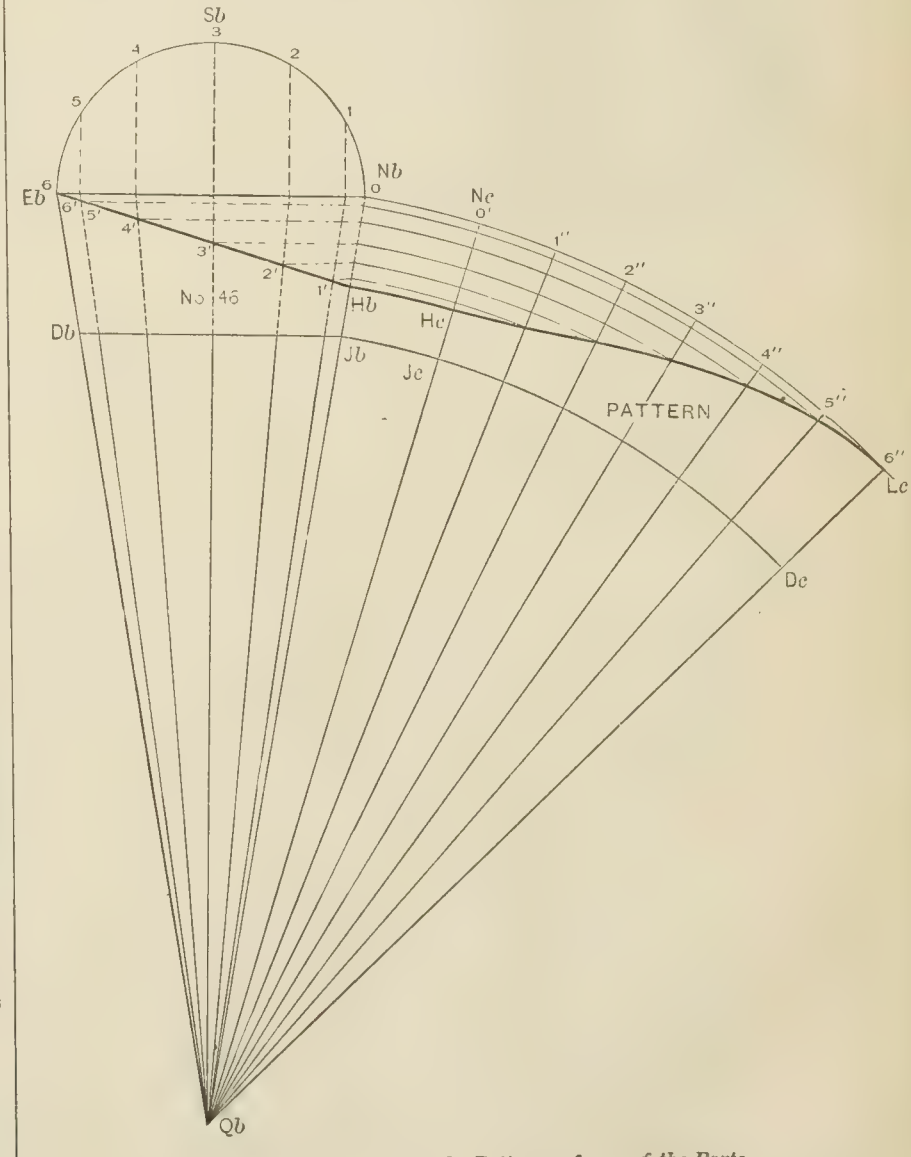

Fig. 4.—Method of Obtaining the Pattern of one of the Parts.

PATTERN FOR SHIP'S VENTILATOR.

As early as 1856 Krupp arranged for a common mess and barracks for unmarried men, and in 1884 made living at them obligatory upon all who are not skilled workmen, or who cannot show that they live with near relatives. The last barracks built at Freistadt was for the accommodation of 1200 men, but one of the wings has been altered for families because a large proportion of the unmarried men are sons of old workmen and live with their parents. The board costs 15 cents a day for persons under 16 years and 19.5 cents a day for older persons, exclusive of bread. The volume in question reports in detail the quantities and cost of food

served for 100 persons, for the midday meal and supper, and thus constitutes an interesting budget. The statement is made that the firm loses money at the rates given unless the barracks are pretty full.

Company Stores.

A co-operative company which had got into trouble in 1868 was taken over by the firm. The main objects of the system are to place cheap and good articles at the service of the employees, and to watch, above all, that no adulterated goods are offered for sale. A strictly cash business is done, in order to encourage economy and keep the men from contracting the habit of borrowing. Since the beginning of 1890 the firm has arranged to return all profits on the store business to the purchasers. A pass-book is issued to every purchaser, in which all cash sales are entered. Before Christmas the profit is distributed pro rata After the first year's operations a profit of 5 per cent. on total sales was paid in cash to buyers. During the fiscal year 1890-91, 8641 employees of the Essen works and 2513 employed at outside establishments participated in this profit.

There are 15 stores in which groceries are sold and 9 for dry goods. Besides, there are shoemakers' shops, a mill and bakery, slaughter house and seven restaurants. Some idea of the magnitude of the business may be obtained from the following list of aggregate sales in 1890:

	Kg.
Wheat flour	934,094
Buckwheat flour	54,800
Beans	91,253
Pease	110,432
Lentils	17,873
Rice	111,861
Lard	112,995
Butter	111,771
Coffee	207,100
Prunes	69,680
Potatoes	963,214

The bakery produced 1,184,886 kg. of black bread, 584,108 kg. of rye bread, 233,523 kg. of wheat bread, 2,505,676 rolls and 1,117,245 "zwieback." During the same year the slaughter house sold 1335 beeves, 1343 calves, 4907 hogs, and 817 sheep. The sales of beer aggregated 1,424,539 liters, while the sales of wine amounted to 167,000 bottles.

Full tabular statements are given concerning the average prices at which the leading articles were sold from 1871 to 1890. As an example, the figures dealing with the latter year may be presented:

	Per 100 pounds. Cents.
Potatoes	65.85
	Per pound.
Black bread	1.59
Beef, first quality	15.06
Beef, second quality	13.96
Veal, first quality	14.55
Veal, second quality	13.45
Mutton, first quality	15.12
Mutton, second quality	13.20
Pork	16.41
Lard	11.00
Butter, first quality	26.14
Wheat flour	3 30
White beans	2.78
Pease	2.99
Lentils	5.17
Rice	3.39
Java coffee	27.32
Salt	2.18
Prunes	5.75
Cube sugar	11 00

Since 1882 an ice factory has been in operation. During the period of May to October a 30-pound block is delivered daily for $7 per season.

Most elaborate arrangements have been made by Krupp to provide for the proper sanitary condition of his men. There is a large hospital. The sick fund, a separate organization, pays 37 cents per day for the support of men, and lower rates for women and children, the firm paying the deficit. During the year 1890-91, with 15,918 persons employed, there were 1192 men and 575 women and children as patients, who remained in the hospital on an average 19.73 days, the hospital cost per workman being $1.86. Provisions have also been made for hospitals for epidemic diseases.

Sick Funds, &c.

A sick and death fund was established as early as 1853. The passage of the law of June 15, 1883, made a reorganization necessary, and two distinct associations were created, one for the support of the sick and one for pensioning the old and disabled. The sick fund is administered even more liberally than the provisions of the famous German law called for. In 1890, with 15,572 members, the dues were 275,496.44 marks. The firm contributed their legal third, or 137,682.91 marks, and 13,374 21 marks were received from outside patients. The outlays included 50,777.18 marks for medical attendance, 63 658.38 marks for drugs, 172,503 31 marks for sick money to members, and 32,851.63 marks to their families. The sums paid to hospitals were 31,994 35 marks; 15,006 marks were laid out for funerals, and 60,000 marks were carried to surplus fund, bringing the total up to 435,435 marks.

Some of the figures submitted by Krupp concerning the pension fund are interesting. The demands upon it under the new law seem to be growing very rapidly. In 1885 110 men drew 46,052 52 marks, 126 widows were paid

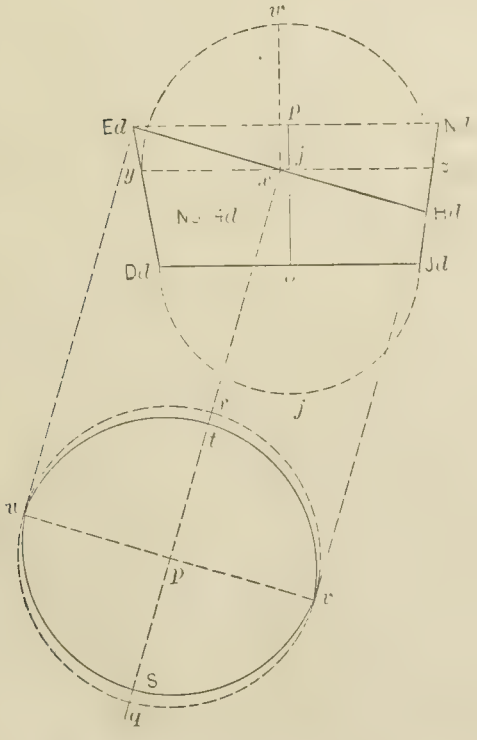

Fig. 5.—Shape on Miter Line Ed Hd.

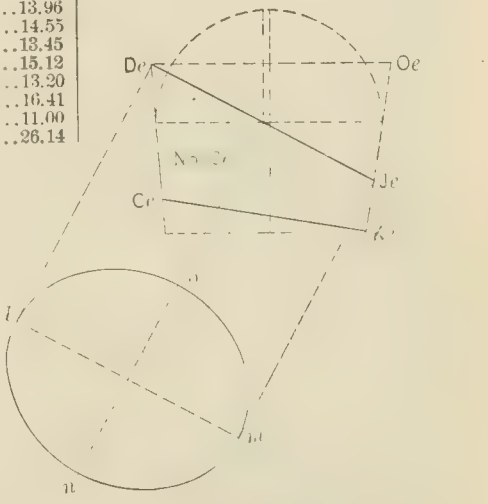

Fig. 6.—Shape on Miter Line De Je.

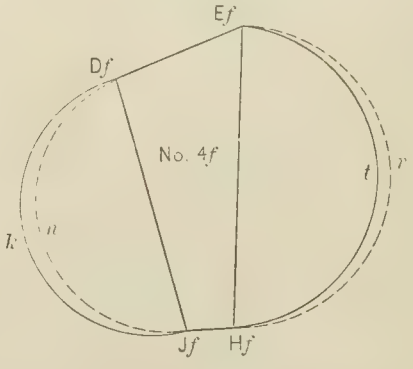

Fig. 7.—The Two Shapes Contrasted.

PATTERN FOR SHIP'S VENTILATOR.

33,655.19 and four orphans 189 92 marks, a total of 79,887.63 marks. In 1890 312 men received 144,053.62 marks, 357 widows drew 93,133 96 marks, 35 orphans 1,687.19 marks, while 15 men drew 1936 marks in partial pensions, carrying the total up to 240,810.77 marks, or roughly $59,000. No idea can yet be formulated concerning the average duration of the pension. Recently three Krupp pensioners have died who had lived 18, 20 and 13 years respectively after being retired from active work.

Lately additional acts have increased the scope and the payments under the pensioning act, and Krupp has accordingly voluntarily increased his annual contribution to the fund from the legal third to one-half, which will carry it to about $60,000 a year. In 1890 the present fund possessed in securities and cash 2,208,851.18 marks. The membership dues were 211,122.47 marks, and the Krupp contribution was 105,561.30 marks. Initiation fees amounted to 21,219.28 marks and interest to 91,196.18 marks. Other sources of income brought the total 440,233.53 marks. The expenditures, including 240,810.77 pension payments, footed up to 249,160.57 marks, leaving a balance to carry to surplus of 191,072.96 marks.

In 1890 E. A. Krupp contributed 500,000 marks to a pension fund for officers of the firm, and provisions have also been made for accident insurance for officers and the better paid employees

In 1887 he subscribed 1,000,000 marks as a fund the income of which is to be used for aid to those employees of the works who have suffered misfortune and whose case is not reached under the present laws.

A sum of 500,000 marks has been donated as a fund for the benefit of the citizens of Essen. The capital will probably be invested in workmen's houses.

In 1877 a life insurance scheme was started and which is prospering.

Comprehensive work has also been done in establishing common schools, which now have an attendance of 1100 scholars, in promoting industrial schools for grown girls, and for teaching household duties to girls. An apprentice system for boys has been long a feature of the works, the principal object being to train good carpenters and masons. Scholarships to the amount of 12,000 marks annually are granted, for aid in attendance at technical colleges. A club house has been built for the officers of the company, who pay low initiation fees and annual dues. Water and gas are furnished to residents of the Krupp houses at cost, the figures being extremely low.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until July 26, for all the labor and materials required for the interior finish, including plumbing, &c., of the United States Court House, Custom House, &c., Building at Duluth, Minn., in accordance with the drawings and specifications, copies of which may be had at the office of the Supervising Architect at Washington, or from the superintendent at Duluth, Minn.

Co-operative farming is greatly in vogue in Denmark. Over 1000 farms are conducted on this principle and are said to be very flourishing.

The Sale of Athletic and Sporting Goods.

BY T. W. STAKE.

THESE GOODS cannot usually be satisfactorily added to a general Hardware stock, unless a special department with a competent manager be started. The line has grown so large and varied, being almost as complicated as a general Hardware stock, that it requires an experienced person to talk intelligently on each subject, such as Guns, Bicycles, Fishing Tackle, Lawn Tennis, Foot Ball, Gymnasium Goods, Base Ball Goods and Athletic Clothing, &c. A salesman in this line particularly must gain the confidence of the sportsman; he can then sell him the goods he recommends, and can take orders for goods he does not carry in stock. Fortunately, the different lines are seasonable at different times in the year, so that the stock can be changed to suit the season; each particular line can be reduced, so that at the end of the year a very small stock is carried over.

THE SEASONS

Are as follows: For spring, Bicycles, Fishing Tackle; for summer, Base Ball, Lawn Tennis, and Fishing Tackle; for fall, Guns, Foot Ball; for winter, Gymnasium Goods, and, I might add, Skates. Revolvers sell in a small way all the year round.

The kind of goods usually sold in Hardware houses with Sporting Goods departments, or exclusive Sporting Goods houses, in my experience as a traveler for ten years and manager of a Sporting Goods department for five years, the size of the stock carried being graded by the size of the town and its locality, is as follows:

Guns.—A few Single Barrel Breech Loaders; a fair line of imported Guns, to sell from $10 to $25; a fair line of American-made Guns, to sell from $25 to $75, and a very small sample line of high-grade imported Guns, from $100 to $250.

Fishing Tackle.—Medium and high grade goods that suit the section of the country. Toy and stationery stores usually sell the common goods.

Bicycles.—Get an agency for a high-grade Wheel, and carry a sample line from $20 to $100. This with a line of sundries is all that is necessary.

Lawn Tennis.—A fair stock of good quality Rackets, with very few common goods; also a good supply of best Balls, with samples of Nets, Markers, &c.

Base Ball.—A complete line of Balls and Bats, but principally good-quality goods; also Mitts and Gloves, as well as Masks, &c.; also sample material for Base-Ball Suitings.

Foot Ball.—A small line of American Rubber Foot Balls, with a better line of Leather Rugby-shape Balls, and a few Association Leather Balls; also samples of Foot-Ball Clothing to take orders from, as this amusement is increasing in popularity.

Gymnasium Goods.—A complete line of Indian Clubs, Dumb Bells, together with a small line of Chest Weights. Have a catalogue of some large maker of Gymnasium Apparatus.

Revolvers.—A complete line, although better goods sell the best.

Skates.—A complete line where the climate permits of skating.

The sale of the goods can be increased by the clerks or partners joining or taking an interest in the clubs in town, thus making the acquaintance and gaining the confidence of the members. It is policy to keep the stock in season in full view—at the front of the store if possible—so that everybody coming in to buy Hardware can see this line easily.

The stock should be kept clean and fresh, especially Bicycles, Guns, Revolvers, Tennis Rackets and Fishing Tackle. Clerks in this department should always dress neatly and keep the store clean. It is good policy for salesmen to show Sporting Goods to customers, even though they are buying other lines.

SHOW WINDOWS.

Goods should be delivered promptly and when taking special orders never promise goods before the time you can deliver them. The display in show windows should be given special attention and changed often, always showing seasonable goods only, and making the windows attractive by adding special features from time to time—such as pictures of crack Bicycle riders, base-ball clubs, prominent foot-ball or tennis players and in the fall mounted animals or any novelty which would attract people. I believe a good percentage of the most profitable business comes from the show windows.

All of the suggestions I mention can be carried out on a small or large scale according to the size of the town. While it may seem that I have mentioned a great many different articles connected with Sporting Goods, still their coming in at different seasons makes the investment rather small at any one time.

THE CATALOGUE ALONE.

I believe in this age of sharp competition it would be difficult to do much business with the catalogue alone, as no person more than a sportsman likes to handle the goods he wants to buy. Still, in very small towns where there is no competition samples of some goods could be carried and orders taken from catalogues for others, but the business must necessarily be small.

Stocks of wheat in the United States last week were returned as 66,376,000 bushels, against 26,006,000 bushels year in the corresponding week of last held.

STOVE TRADE NOTES.

World's Fair Exhibits.

Cooking and Heating Apparatus.

THE MAGEE FURNACE COMPANY

of Boston have an exceptionally fine exhibit at the World's Fair. They not only erected a pretty pavilion, but introduced some clever features with it that are very effective. The floor, for instance, is tiled in two colors in two levels. Red unglazed tile is used for the center, which is in the form of a circle, so large in its sweep that the space left around it is just wide enough for a stove platform. The platform is tiled in cream glaze, with an oak border Potted plants are tastefully arranged among the stoves. The pavilion is built of antique oak posts, with a muslin canopy gracefully caught up in the center, from which also hangs a fine electrolier, while heavy ornamental rope is festooned from post to post for a railing. The goods shown are gotten up very attractively. The new Magee Grand range is placed on a tiled platform in the center of the pavilion as the leader. It is a magnificent piece of work from the standpoint of artistic molding. The motive of the molding is leaf work, the high surface being beautifully nickeled, making a sharp contrast with the quiet black background. This range has some peculiar features apart from its beauty. There is a plate on the end of the fire box, fastened by pins, which when removed enables the grate to be drawn out for repairs without disturbing the linings.

The Dockash grate is used. The oven door is ventilated, as has always been the practice of this company, but a new device is a thermometer on the oven door. It is a circular metal thermometer, set in the place of the usual tile. It is useful to show the temperature of the oven, but at the same time adds to the decorative appearance. The water front for this range has a tube projecting from the center horizontally into the fire box, which greatly increases the water-heating power without detracting from the efficiency of the fire. All the other modern improvements and conveniences have been incorporated in getting up this range, which is made in any style desired. Other goods shown are the Ideal open heater, new last year, now provided with a shaking, draw-center grate; the Ideal square self feeder, a standard stove for the past 12 years; the Mystic six-hole range, shown in several styles and sizes; the Mistletoe sheet-iron surface burner; the Standard oval heater; the Royal Standard square sheet-iron heater; the six-hole Home Kitchener range, which is adapted to brick setting or for portable use; the double-oven Mystic range; the Magee Standard six hole range, one of the company's oldest patterns, but improved with the progress of the times; the Hotel Kitchener eight hole double-oven range, with high and low warming closets, intended to be brick set or portable, shown connected with a boiler just as it is set for use; the Boston wrought iron warm-air furnace, with casing partly removed to enable the interior construction to be seen, and the Boston combination warm-air and hot-water heater, also partly unjacketed to show the interior construction.

HOWARD THERMOSTAT COMPANY

of Syracuse N. Y., exhibit their device as attached to a furnace. The thermostat is placed some distance above the furnace, fastened to a post. Chains pass from it to the furnace damper over pulleys. So sensitive are the metals forming the thermostat that the heat of a lighted match is sufficient to instantly cause the damper to move, closing the draft side and opening the check side. The damper is an ingenious device, being a brass cylinder 8½ inches long and 10½ inches in diameter, with a partition through the center, dividing the draft from the check. Slots extend lengthwise through the cylinder, those on the check side alternating between those on the draft side. This damper is placed in a horizontal pipe on the exterior of the bottom of the furnace, with the check and draft sides properly connected with the furnace. It revolves on a pivot, so that it is easily moved by the thermostat, which has no working parts about it to get out of order, depending entirely for its action upon the expansion and contraction of very sensitive metals.

RIDGWAY FURNACE COMPANY

of 76 Union street, Boston, exhibit the Ridgway revolving open fire pot heater. The specimen shown has the jacket partly removed, to enable the interior construction to be easily comprehended by the observer. In this furnace the grate remains stationary, while the fire pot can be turned by means of a crank placed at a convenient hight, the pot revolving on balls, which bear on perfectly flat surfaces. It is claimed that the ashes are scraped from the fire without massing the coals, that the combustion of fuel is complete, that there is no waste of unconsumed coal, that direct radiation is had from the sides of the fire as well as the top, that slow fires are easily maintained and that putting on coal does not smother or retard the fire. A gold medal was awarded this furnace in 1892 by the Massachusetts Charitable Mechanic Association for superiority and economy, being the highest award given a furnace for over 35 years.

W. A. DAGGETT & CO.

of Vineland, N. J., with a number of branch offices in leading cities, exhibit Daggett's patent Russia iron, self basting roaster and baking pan. This pan is an old and well-known article in culinary circles, intended for roasting poultry, meats and fish, and baking bread, cake, puddings, beans, &c. It is made in eight sizes. The manufacturers state that over 500,000 have been sold.

P. T. BENBOW,

1814 and 1816 North Eighteenth street, St. Louis, exhibits a self-heating washer, which is a washing machine of the square type with a gasoline stove attachment to heat the water used. The bottom of the washer is of galvanized iron, and the burner under it heats the water quickly. The clothes are moved over rollers in a "roller bed" above the bottom of the box by a rubboard, with holes in it to cause a suction which forces the suds back and forth. The special claim made for this machine is that it can be used anywhere, so that washing can be done in the coolest and most pleasant spot available. The stove, being portable, goes with the washer, instead of the washwoman being compelled to work in a hot kitchen to boil her clothes on the cook stove. The gasoline stove can be detached and used for other purposes when not needed for operating the washer.

B. B. JOHNS,

12 North Seventh street, Philadelphia, has an exhibit of stove polish. A toy stove on a high stand serves to point the moral and adorn the tale of this exhibit.

The Fuller-Warren Company.

We are indebted to the Fuller-Warren Company, Milwaukee, Wis., for a copy of an exceedingly attractive catalogue of the line of stoves, furnaces and ranges made by them. The volume is issued in book form, having 160 pages, bound in stiff board covers with side titles in black and silver letters. The printing is in two colors, the body of the page being in black, while in the upper outer corner of each page is an ornamental piece, embracing the letters "F. W. Co.," and brief reference to the line of goods manufactured. A telegraphic code, an illustrated description of the patent oval fire box used in the company's ranges, and of the direct damper arrangement employed, are features of the opening pages. The F. & W. Co. Stewart range for 1893 is first considered, following which we find the Matchless, the Signal Stewart, Royal Diamond and National Diamond ranges, made in several styles and sizes and embodying the modern improvements. The F. & W. Co. wrought-steel range is shown in several modifications, while descriptive letterpress tells the number of sizes in which it is made, the dimensions of the oven and code words for convenience in ordering by wire. A long line of attractive cook stoves is presented under such names as Stewart, Signal Diamond, National Diamond and Popular Diamond. The heating stoves occupy about one-half of the catalogue, the leading place being given to the P. P. Stewart base burner for 1893. This stove met with a large sale last season, which justifies the makers in believing that, with the new improvements which have been since added, it will continue to take high rank in the estimation of the trade. The Splendid base burner for 1893 is a new heater for this year, fitted with Ransom's combination duplex grate, patent sectional fire pot, swing top with automatic acting magazine cover, large hot-air flue circulation and handsome finish. The F. W. Company Splendid for 1893 is made in two sizes

for anthracite coal and has had new base skirting added for this season. At the request of many of their customers the company have incorporated in this year's catalogue a brief sketch of P. P. Stewart, after whom several of the stoves made by the company are named. A varied assortment of oak, globe, cannon, laundry, box, Todd, cottage parlor and Franklin stoves contribute to the general line of goods shown. The catalogue concludes with an illustrated notice of the furnaces made by the company, suggestions for ordering repairs, price-list of fire brick and a general index.

The Royal Aladdin Base Burner.

Burdett, Smith & Co. of Troy and Chicago have just placed upon the market a new base burner known as the Royal Aladdin. It is one of the handsomest heaters which the firm have ever produced, the patterns being entirely new and many improvements embodied which are not usually found in stoves of this style. The ornamentation is rich and artistic, the proportions graceful and the general design of a character to please the eye. Nickel has been judiciously employed to produce the desired effects, while the large area of mica illumination gives to the stove when in operation a bright and brilliant appearance. The manufacturers refer especially to the excellent workmanship on the patterns, the beauty of the castings and the manner in which the parts are put together. Constructively, the Royal Aladdin is an excellent example of the best type of the modern base burner. The fire pot and grate are so disposed that they can be easily removed for repairs. By the simple loosening of two bolts in the central ring the front half is detached, when the fire pot can be drawn out through the front without trouble. The stove is also fitted with the Ransom duplex grate, which can be operated in such a manner as to slightly shake the portions of the fire around the outside of the fire pot where most needed, while clinkers can be cut out of the center. The fire pot can also be cleaned of ashes at the bottom when necessary. One of the important features of the stove is the system of hot-air circulation. This is accomplished by means of a large flue on the back of the stove, between the main flues. This flue extends from the base to the tea-kettle section, then divides into two flues on either side to the extension dome at the top, where the hot air is discharged into the room. The back plate forming the heating flues is cast in one piece, with a hollow section between the flues, which, when covered by a loose plate, forms a circulating flue without puttied joints. This is entirely outside of the stove, and thus avoids any possible escape of gas into the room. The makers also claim that the arrangement gives a large heating surface to the circulating flue, and, as the cold air drawn through it from the floor passes through the stove in a highly heated condition, a constant circulation is maintained. A feature of the illumination is found in the contour of the mica sections, both upper and lower of which are made on curved lines instead of straight. This, it is said, increases the illuminating power of the doors, which, with the swell of the front, gives a spherical effect to the body of the stove and adds greatly to the illumination of the fire, as well as increasing its radiating power. The nickel parts of the stove have been constructed with a view to simplicity of arrangement and they can be easily packed and protected for shipping or storing. This feature is much appreciated by dealers handling the stoves, as great economy of time results thereby. The stove is so made in all its parts that there are no joints visible in the front or sides.

The Future of the Hot-Air Furnace.

By A. W. Gleßner.

President of the Excelsior Steel Furnace Company, Chicago, Ill.

In a former article on the above subject I referred to the increased interest taken by dealers in hot-air furnaces in the science of such heating, with the result that the standard of furnace work is being constantly raised from year to year. This interest, while deeper now than formerly, is not new in the trade, and in evidence I refer to *The Metal Worker* competition in house heating by furnaces which took place some years ago, and which brought out papers and opinions from dealers in various parts of the country, though chiefly from the territory east of the Mississippi, showing that dealers at that time were alive to the importance of a thorough knowledge of hot-air heating. Should this competition be repeated it would be found that the interest in it had extended in the interim to points in remote corners of this country where five years ago a furnace was unknown. Dealers have learned that to do good work a furnace must be properly located and set, and that careful study must be given to each job if the best possible results are to be obtained. That furnace dealers are aware of these facts is apparent from the demand that has set in for literature on the subject of hot-air heating, and also for the number of plans that are sent to the leading furnace makers with requests for information in regard to the size of furnace, location of same, together with the locations and positions of the connecting pipes and registers, in order that the buildings contemplated in these plans shall be thoroughly heated. Nor is this interest confined to the dealer alone nor to the house owner, but it has spread to the architect and builder, and rarely a day passes that does not bring to the office of our company a set or sets of plans from architects and builders requesting that the heating be diagrammed, and the prospect is that in the near future we will be compelled to organize a department devoted to this class of work.

The interest taken by the architect or builder and his apparent willingness at the present time to co-operate with the heating contractor augurs well for the future of the hot air furnace, for the time was, and not very long ago, either, when no consideration was given by either architect or builder to the heating, and no provision was made for the concealed pipes, with the result that when the heating was to be installed the building had to be cut and hacked to pieces to find places for the pipes, whereas a little planning and forethought would have provided the channels needed without extra expense in material and very little additional labor. All architects are not showing a disposition to consider the heating contractor, and, indeed, the percentage of architects who are evincing such a disposition is still very small, but everything points to a general change in the position taken by the architect and builder in the past, and a time is surely coming when the architect will consider the heating fully as much as he now considers the foundation or plumbing.

The dealer in furnaces, by becoming posted on the principles of hot-air heating, is able to impress upon the architects with whom he comes in contact in his work the importance of correct planning in advance of construction, and gradually the architects will wheel into line.

What the Manufacturer is Doing.

The manufacturer of hot-air furnaces is doing not a little to advance the interests of the dealer by supplying him not only with better goods than formerly, but also has provided not a little help in the way of useful hints through the salesman and printed matter sent out to the trade. While this help has been gratuitous and sometimes without great value, it has all helped to educate the dealer and to improve the standard of work done, and thus has led to a larger sale for the heaters made. It is of great importance to the trade that all work that is done is done well, for the reason that one bad job in a town reflects discredit upon the hot-air heating as a class, and often leads to the introduction of other methods of heating.

An examination of the catalogues sent out by the furnace makers does not indicate that the hot-air furnace is in its dotage. Each year's edition exceeds in size and completeness the productions of the preceding year and shows a constantly increasing list of satisfied users of the apparatus, which does not coincide with the view expressed by the stove makers. Of course these catalogues do not give the names of the dissatisfied buyers, but in proportion to the number of purchasers I incline to believe that the percentage of the malcontents would be fully as small as in any other branch of heating.

More detailed information is given in these catalogues than formerly, and in one or two plans are given showing the location of furnaces and registers.

One manufacturer has expended this season more than $3000 on a catalogue in an endeavor to supply accurate information regarding hot-air heating in general, and *The Metal Worker* has reproduced a good portion of this work. All this indicates a faith in the future of hot-air heating, and if anything more convincing is needed it can possibly be found in the sales of furnaces, to which I expect to refer later.

(*To be continued.*)

The Sill Stove Works.

One of the neatest stove catalogues which have recently come to hand is that issued by the Sill Stove Works of Rochester, N. Y. It is of a size to render it especially convenient for reference, while the arrangement of the matter gives evidence of careful attention to details and due consideration of the requirements of the stove dealer. It is nicely printed on a good quality of paper and bound in flexible cloth covers of a deep green shade. The first 63 pages are given up to a presentation of the leading styles of the Sterling line of ranges. The goods presented embrace four complete lines of six-hole ranges and one of four-hole ranges. The Sterling is a first-class construction embodying the latest features, one of the special points being the transparent ventilating double oven door. The inner or transparent door has around the outer edge of the mica frame an opening through which the air passes

into the oven. This does not allow cold air directly into the oven, as before it reaches the openings it comes in contact with the warm air which is inclosed between the two parts which constitute the double door. Perforations in the back oven plate allow the air in the oven to escape to a flue which carries it to the chimney. When the two doors are closed the appearance is that of an ordinary oven door, but when the outer portion is open the contents of the oven can be readily seen without danger of lowering the temperature of the oven. The Quick Sterling six-hole, the Home Sterling and the Quick Sterling four-hole are the names under which some of the other goods are made. An interesting feature of this catalogue is an illustrated description of the lock center employed, as well as of the plunge damper and of the sectional cover used in connection with the Sterling goods. The wood cooks include the Bright Sterling, Humbert and Amity, while those adapted for burning coal or wood include the Star Sterling and the Sterling "E." The heating stoves occupy the closing portions of the catalogue, and are represented by the Sterling Ventilator, which is in its sixth year; the Silver Sterling, a new construction to which reference has already been made in these columns; the Parlor Sterling, a medium-priced heater; Ideal Sterling, a low priced construction; the Advance, a neat cottage parlor stove made in several sizes; the Sterling Cottage, made in two sizes direct draft and two sizes with return flue; the Champion, a neat box stove for wood only, and the Torpedo, an all-cast cannon stove in five sizes. A price-list of brick linings, mica and sundries, an index to the code words and a general and alphabetical index are features of the catalogue.

ODD PLATES.

Egley Bros., Onarga, Ill., have issued a neat little catalogue descriptive of the Owen patent wood stove, which they manufacture. This is a stove of similar appearance to the well known Todd type. It is furnished plain or with a nickel foot rail along one side and nickel horns on the top at the front and at back. The flue construction is such as to compel the heat to pass entirely round the stove. The manufacturers state that it will retain fire from one to three days. The catalogue contains cuts of the separate parts of the stove, numbered for the convenience of patrons in ordering repairs.

The Michigan Stove Company favor us with one of the perpetual desk calendars which they are now distributing to the trade. There are three circles on a beautifully lithographed card, a large circle for days of the month and two small circles for months of the year and days of the week. Ornamental pointers are eyeletted in the center of each circle, to be moved with the change of date. The card is braced to stand upright. The conception is very pretty, and the souvenir will be appreciated by those into whose hands it may fall.

James Boyle & Co., Salem, Ohio, send us a calendar for the month of July, embellished with a general view of their Perfect Oak. This is an attractive construction embodying the modern features, and is offered the trade as a powerful heater. All the doors of the stove are fitted against lap joints, the doors being fastened with turnkeys and latches. Beneath the picture of the stove is a calendar for the month, the printing being in dark green ink on a white ground. The name of the company and of the stove, together with the address of the agents for the Northwest, are printed in red. The grate for coal is of the shaking and dumping type, while that for wood is a double cut-off grate having special shaking arrangement. The ash pan is extra large and all draft slides are wedged so that when closed they are air tight. The manufacturers guarantee this stove to keep a wood fire over night. It is offered the trade in four sizes, Nos. 12, 14, 16 and 18.

The Barstow Stove Company are keeping up their reputation as distributors of 4th of July advertising novelties. We received from them during the early part of the week what at first glance appeared to be a large powder cracker, it being flat, however, instead of round. Untying the string forming the fuse we found that the device consisted of a folder, on the inside of which was the name and address of the company, together with advertising matter relative to the Bay State furnaces, ranges and stoves. It was also stated that "Independence in trade is often as important to individuals as independence has been to our great American nation. It frequently depends upon the line of goods handled as to how soon the stove dealer may become financially independent." The device is copyrighted by the Livermore & Knight Company of Providence, R I., and is in keeping with many other novelties which they have gotten out.

S. R. Wells, Indianapolis, Ind., is sending out circulars of the Model Oak, a new stove made in four sizes. The features include an ash pit cast in one piece and having a screw-wheel damper in the ash door. All doors are tightly fitted and the air supply to the fire can be adjusted very closely, so that a guarantee is made that a fire can be kept at least 48 hours. The new Model Gas is another novelty, adapted for either coal or gas, and having, in addition to the burner, a draw-center grate, fire-clay linings and a fire-clay deflector. It is made plain and richly ornamented with nickel and tile pilasters, nickel top ring, nickel dome, nickel urn and a nickel foot rail.

Stoves are not the only production of the Indianapolis Stove Company, Indianapolis, Ind., for a fine line of ground hollow ware greets the eye of the customer as he goes through their showrooms. Their new line of oak stoves is known as the Columbia, and in style of carving and nickel trimmings is worthy of the Columbian year. Not finding our friend Bennett on deck when we called, we enjoyed the hospitality of the house dispensed by other hands.

The Western Stove Works of Peoria, Ill., refer to their Lake View Oak parlor stove as possessing features peculiarly its own. No bolts are employed in fastening the foot rails to the stove, as they are secured in place by wedged lugs. The fret work jacket is easily removed when necessary to polish it, the ash pan is large, the fire pot heavy, and the adjustable damper in the pipe collar of such a character as to give perfect control of the fire.

At a meeting of the stockholders of the Girard Stove & Foundry Company, held on the evening of Tuesday, June 27, the following directors were elected: H. B. Shields, Thomas Parrock, Frank Williams, W. J. Wallace, B. F. Briggs, William Fair and Edward Kennedy. The directors then held a meeting and elected H B. Shields president, Thomas Parrock vice-president, Frank Williams secretary and treasurer, W. J. Wallace general manager and B. F. Briggs superintendent sales department.

Kruse & Dewenter, Indianapolis, Ind., are still hearing good reports from their furnaces and the service rendered last winter. A point they always endeavor to clearly demonstrate to a prospective buyer is that furnaces of large capacity are more economical and cheaper in the end. In consequence their wrought-steel warm-air furnaces are increasing in popularity.

Recently the Excelsior Quartette of Troy, N. Y., gave an enjoyable concert and were royally entertained at the residence of W. A. Clark of the Phillips & Clark Stove Company at Geneva, N. Y.

F. M. Borden & Bro., Philadelphia, though still occupied in sending out gasoline stoves and refrigerators, are preparing for the fall. This year finds them with a full line of the Novelty stoves as leaders, and the line of Leaf stoves will not be the second choice with many buyers.

Several thousand "What's Inside" circulars were distributed at the Industrial parade, at Tamaqua, Pa., on the Fourth by E. J. Fry. The inside pages showed some of the handsomest and best of the Novelty stoves and ranges made by the Abram Cox Stove Company of Philadelphia.

J. H. Nevins of the Laura Nevins Range & Heating Company, St. Paul, Minn., informs us that among recent orders taken by him at the World's Fair, Chicago, were the following: One range, to be shipped to G. D. Y. Scholtz, Claremont, Cape Town, South Africa, and two ranges to P. T. D. Wessels of the same place.

The Chicago Foundry Supply Company, whose Peerless Facing Mills are at Eighteenth and Rockwell streets, Chicago, have opened an office at 503 Teutonic Building, southeast corner of Washington street and Fifth avenue, in that city. They invite visiting foundrymen to call upon them at this central location, where every facility will be provided for attention to needed correspondence. The favor will doubtless be acceptable to many of those who are now making the pilgrimage to the World's Fair.

The Abram Cox Stove Company of Philadelphia are preparing to remove their offices and salesrooms, at present established on North Second street, in that city, to the new building adjoining their Dauphin and American streets foundry. We understand that the building will be ready for occupancy about the end of the present month. The new building is of brick and covers an area 45 x 450 feet, and with its six floors will afford about 125,000 square feet of floor space.

George M. Clark & Co , 153 to 161 Superior street, Chicago, seem to be among the few large establishments not affected by the depressed trade conditions. Their orders for gas and gasoline stoves and ranges are considerably ahead of last year, and they have recently been obliged to assume occupancy of another floor in their factory building to increase their facilities. Their business so steadily increases that it will be but a question of time when they will outgrow the accommodations at their present

location. They have a fine collection of their goods on exhibition at the World's Fair in the Manufactures and Liberal Arts Building, northeast quarter, Section O, Block 3, No. 76. In connection with this exhibit they are distributing what they term "A True Guide Through the World's Fair Grounds." It is only a leaflet, which can be put in the pocket without folding, but it gives a diagram of the grounds, and names all the points of interest.

W. H Switzer of the Superior Furnace Company, Little Falls, N. Y., passed through Chicago last week on his way home from a four weeks' trip, during which he had visited 24 large cities, from St. Paul to Portland, Ore., and from San Francisco back to Chicago. His trip he reports very successful, in view of the depressing financial conditions. Dealers throughout the West complain that business has been much interfered with; but in all parts, except in the silver producing sections, the opinion prevails that the worst has been passed and a good trade is expected during the late summer and fall months. Mr. Switzer has formed connections in many of the new and prosperous towns in Western territory for the Superior furnace, and is much encouraged over both the present condition and future prospects.

"Miscellaneous Catalogue No. 2," issued by J. W. Paxson & Co., Philadelphia, relates to foundry supplies and equipment, and gives a very full list of miscellaneous goods of this sort that will be of interest to molders generally. The pamphlet, of small size, contains some 40 pages of letterpress, is bound in paper covers, and illustrates and briefly describes, besides giving a price-list, an extensive line of foundry supplies. Drying stoves, lamps, bellows, brushes, clamps, crucibles with rammers, shovels, patent letters, buckets, watering pots, chaplets, flasks of various sorts, barrows, emery, core oven, griddles, stove cement, Dr. Kirk's chemical compound and similar goods are included.

The adjourned meeting of the stockholders of the MacKellar Foundry Facing & Supply Company was held at the company's office at Quincy, Ill, on Monday, the 3d inst. The following directors were elected: James Woodruff, Gen. James D. Morgan, M. K. Weems, W. H. MacKellar and W. H. Woodruff. The directors then elected the following officers to serve the ensuing year: President, James Woodruff; treasurer, M. K. Weems; secretary, J. R. Woodruff. James L. Haight was appointed superintendent of manufacture *vice* W. H. MacKellar, whose resignation was accepted by the directors at their meeting on May 1. This company report a successful business for the past year and a bright outlook for the future, owing to the improvement in quality of their facings, made under the direction of Mr. Haight.

We are indebted to secretary D. M. Thomas for a copy of the pamphlet containing the minutes of the eighth annual meeting of the Stove Founders' Association held at Chicago, May 30 of the present year. It is a work of 20 pages, bound in colored paper covers, and in addition to the minutes of the association named, there is presented the address of president Henry Cribben.

"What's Inside?" is the query embossed in gold on the front of the very handsome set of gilt-edged photo-tablets which the Abram Cox Stove Company of Philadelphia are sending out to the trade. The set consists of five gilt-edged tablets, each 6½ x 4½ inches, the whole fastened by a blue silk cord in such a manner as to allow of opening lengthwise. Four of the tablets contain burnished photo-engravings of the company's leaders in the line of base-burning square heaters, the Radiant Novelty, Parlor Novelty, Palace Novelty and Starling. The back of each tablet preceding the pictures is devoted to a description of the stove facing it, with a list of prices. A somewhat novel semi-circular thumb indent is cut at the foot of each tablet, and the name of the stove appears immediately above it. The familiar trade symbol adopted by the company occupies the back of the last tablet in the set.

The Leaf Stove Company of Philipsburgh, N. J, are sending out to the trade a handsome card folder, containing a photo print of the Maple Leaf range. The page opposite the print announces that the Maple Leaf is the initial number of a series of first-class ranges and stoves which the company purpose offering to the trade this season. A typewritten circular letter is inclosed with the folder, calling attention to the new range and fully describing it. The Maple Leaf, it is claimed, has large sheet flues, correctly proportioned fire box, perfect working duplex grate, a large ash pit, top plate cut in four pieces, crosspieces heavy and braced, long centers cut and reversible and heavy covers, with ribs on the side exposed to the fire, making them proof against cracking or warping. The range is also provided with a hot-air attachment. While the Maple Leaf will be their leader in the six-hole range line, the Holly Leaf will be their leader in the five-hole styles. Both ranges are now ready for the market. The company expect to have ready for the market, in August next, the Ivy Leaf, which they state will be a base burner of first-class design. All the productions of the company will be sold under the general surname—Leaf.

The Grander Stove Company, with office and works at Royersford, Pa., are vigorously pushing the sale of their square parlor heater known as the Mars. It is made either straight draft or full revertible flue, and is offered to the trade in three sizes. The stove is cheap in price but of first-class construction and is tastefully ornamented with nickel and art tile. The company are also directing attention to the Volga, a double heater made in two sizes with full revertible flue. It is of neat design and embodies, among other features, the latest improved grate, dust flue and parts so arranged that a section of the front of the stove can be detached, thus making the removal of the magazine very easy. In their announcement this week the company state that they will send, on application, circulars giving prices and description.

The many friends in the stove trade of W. E. Hopkin will be glad to know that a cordial welcome at his hands awaits them at the house of F. M. Borden & Bro., Philadelphia, where, as general superintendent, his training and experience will find a scope for usefulness.

The stove and hardware men added no small part to the success of the celebration at Troy, N. Y., on Independence Day. R. C. Reynolds had several floats, one of which carried several styles of handsome Gold Coin stoves. One of H. D. Hull's handsome wagons contained a fine display of his oil stoves in various designs. The Phillips & Clark Stove Company had a float 8 x 15 feet in dimensions, on which were displayed a variety of designs in the stoves manufactured by that concern. An orchestra also rode on the float and discoursed pretty music. The attendants to the horses were attired in Indian costume. Two carriages contained the traveling representatives of the firm, and in others were the local stove dealers. W. E Sandbam made a fine display of stoves and ranges, fully nickel plated. George H. Cole had two floats, one displaying nickel-plated stoves and ranges, and the other a line of gasoline stoves.

A reminder that the baseball season is on us has come in the shape of a score card from the Michigan Stove Company. It can be used as a counter for other games as well, consisting of two cardboard disks, which revolve between two other pieces of cardboard. Figures on the disks show through holes in the frame.

The Kelsey Furnace Company, Syracuse, N. Y., have established their Western agency with the Cook Range & Stove Company of 173 Lake street, Chicago, instead of their former agency at Evanston, Ill. The new agents are so familiar with this line of business that their indorsement of the products of the Kelsey Furnace Company by taking the agency is referred to as evidence of the merits of the goods.

George M. Clark & Co, 153 to 161 Superior street, Chicago, send us a very pretty catalogue of the Jewel gas stoves. The matter is neatly printed on a good quality of paper, and the binding is in colored covers of attractive design. In their annual greeting to the trade, the company state that they have added 11 entirely new gas appliances to their assortment this year, and have remodeled two, so that they are practically new. The opening pages of the catalogue are devoted to Jewel gas burners, which are shown in great variety, following which attention is invited to the Jewel ranges. These are offered in great variety and are exceedingly neat and tasteful in appearance. Nos. 350 to 353 cover a line which the company have just added to their assortment, and these embody all the latest improvements. At the left side of the range is a water back, while at the right is a large warming oven having a long solid burner, and above this, in the upper part of a broiling chamber, is a reversible burner with three caps. The body of the range has a large baking oven with a large roasting oven below. Between them is a set of two burners with four caps each and a pilot light. A variety of Jewel step stoves, Jewel laundry stoves, junior stoves and table stoves are also illustrated and described, together with the Jewel circulating water heater, Jewel baking plates, waffle irons, steam cookers, egg bakers, heating stoves and stove connections. An index to the catalogue is a feature of the closing pages.

The president of the British Institute of Mining Engineers, at a recent meeting of that body, stated that over $720,000,000 was invested in British mines, exclusive of the rolling stock required to convey the produce to its destination. He also estimated that 3,000,000 persons in the United Kingdom were directly dependent upon the mining industry for a livelihood.

TRADE REPORT.

The Iron Market.

The first half of 1893 will be long remembered as one of the most trying that the Iron trade has ever experienced. Transactions during the past week have, naturally, been on a very limited scale, so that the temper of the markets has not been tested sufficiently to judge of their tendencies. Pittsburgh advices indicate that there will be no prolonged shut down of the local mills, and while the chances are that the Valleys and the Chicago and St. Louis districts will follow the lead of Pittsburgh, there is still some possibility of a contest. The Sheet manufacturers and the workmen have agreed upon a scale which is practically the same as the one in force last year.

The stove trade has been in good shape, with an exceedingly favorable outlook for the coming season's business. The depression, therefore, is not owing to any lack of business, but to the exceedingly low prices, and more recently to the disturbed condition of the money market.

Pig Iron.— Current business in the New York market is very light, and although makers of standard Northern brands acknowledge that they are accumulating Iron, they report that it is confined to the lower grades, and that the Foundry Irons are moving off in a satisfactory manner. Intimations are thrown out that Southern furnace interests may reach some agreement concerning concerted action in reducing output. We quote Northern brands at $14.50 @ $15 for No. 1; $13.75 @ $14.50 for No. 2, at tidewater. Southern Iron, same delivery, $13.75 @ $14 50 for No. 1; $12.50 @ $13.50 for No. 2; $12 @ $12.25 for No. 3; $12.25 @ $12.50 for No. 2 Soft, and $12.75 @ $13.25 for No. 1 Soft.

Quotations have changed very little in the Philadelphia market during the past six months, although there has been some variation in selling prices. Taking the entire six months it is not likely that prices have gone either higher or lower than $14.50 @ $15.50 for best brands of No. 1 Foundry, $13.75 @ $14.25 for No. 2, and $12.75 @ $13.25 for Gray Forge, and $12 @ $12.25 for Alabama Irons. Ordinary grades (or in the case of forced sales) may have sold at 50¢ @ 75¢ less, but the figures named give a fair average for the various brands of standard Irons during the period under review.

There is no buying being done in Pittsburgh markets, and with production going steadily on, stocks are being increased and prices are showing a much weaker tendency. Prices quoted are merely nominal, as there are no sales being made on which to base quotations.

No. 1 Foundry	$13 50 @	$13.75	cash.
No. 2 Foundry	12.50 @	12.75	"
Charcoal Foundry No. 1	17.00 @	18 00	"
Charcoal Foundry No. 2	16.50 @	17.00	"

At Chicago the only transactions reported during the past week covered moderate quantities of Local Coke. The full effect of the large contracts placed the previous week has not yet been felt by the Iron trade, as it would require some little time for such information to get disseminated. The following quotations represent the range of asking prices, Chicago delivery, but they are still subject to concessions in nearly every case for immediate delivery and prompt cash:

Lake Superior Charcoal	$16.00 @	$16.25
Local Coke Foundry, No. 1	13 50 @	14.00
Local Coke Foundry, No. 2	13.00 @	13.25
Local Coke Foundry, No. 3	12.75 @	13.00
Local Scotch	14.0 @	15.00
Ohio Strong Softeners	15.75 @	16.25
Southern Silvery, No. 1	@	14 50
Southern Silvery, No. 2	@	14.00
Southern Coke, No. 2	12.75 @	13.00
Southern Coke, No. 3	12.25 @	12.50
Southern, No. 1, Soft	12.75 @	13.00
Southern, No. 2, Soft	12.25 @	12.50
Southern Gray Forge	11 75 @	12.00
Tennessee Charcoal, No. 1	16.50 @	17.00
Alabama Car Wheel	@	18.85
Coke Bessemer	14.50 @	15.00
Hocking Valley, No. 1	16 75 @	17.00
Jackson County Silvery	16.75 @	17.00

In the Southern markets there has been a light volume of business in Pig Iron during the month, but the general conditions do not appear to be any worse. Buyers in easy financial condition have made some purchases on favorable terms, but the exact figures accepted for cash are not made public, while the strong Iron companies in the South are contending for full prices in the regular way. Quotations are as follows:

Foundry.

Southern Coke, No. 1	$13.00 @	$13.25
Southern Coke, No. 2	11.50 @	11.75
Southern Coke, No. 3	11.00 @	11.25
Ohio Soft Stone Coal, No. 1	16.00 @	16.25
Ohio Soft Stone Coal, No. 2	15.00 @	15.25
Lake Superior Coke No. 1	15.00 @	15.25
Lake Superior Coke No. 2	14.00 @	14.25
Hanging Rock Charcoal, No. 1	18.50 @	19.00
Hanging Rock Charcoal, No. 2	17.50 @	18.00
Tennessee and Alabama Charcoal, No. 1	15.00 @	15.50
Tennessee and Alabama Charcoal, No. 2	14.00 @	14.50

Metal Market.

Copper.—The buying has been extremely conservative and the demand has continued tame in the face of the report that nearly all American producers outside of the Tamarack, Boston and Montana and allied interests have signed the international agreement to restrict production and limit exports from this side of the Atlantic during the balance of the year. In short, the appearances are that there is still more than enough Copper of all kinds to meet home trade and export wants, since consumptive requirements are disappointing as far as volume is concerned, while export buying is tame in all that the term implies.

Pig Tin.—The winding up of old contracts has been the most conspicuous feature in the speculative branch of the market and the outcome shows that operators on the long side have fared the worst not only on July but on August options. July went as low as 18.85¢ under pressure to realize, and August to 19.30¢ @ 19 35¢ in the face of cable advices indicating some recovery from late depression in London.

Pig Lead.—The real and threatened shut down of silver mines, along with recent clearance of surplus stocks of Lead at Western points, has served to stiffen prices considerably. At the present time 3.55¢ would appear to be a strictly inside price, and 3.60¢ stands as the general quotation for common Western, while offerings of other than comparatively small lots for prompt delivery or immediate shipment are extremely reserved. There is no inclination to entertain offers on August or later deliveries except at very stiff prices.

Spelter.—Ordinary Western brands have been offered quite freely at 4.20¢ landed here, but, aside from single carload lots occasionally, no sales were effected and the market remains in a dull flat condition. Orders were solicited for larger quantities at 4.15¢, with anything but satisfactory results. As the above outline would indicate, the market is still in poor shape and the undercurrent is highly suggestive of weak position.

Antimony.—The demand has continued slow and the market is still rather weak, with sellers of wholesale quantities at about 9⅞¢ for Hallett's, 10⅛¢ @ 10¼¢ for L X, and 10½¢ for Cookson's.

Tin Plate.—Slow trade and irregularity of prices, with the tendency in buyer's favor, is about all that can be reported. Interest in future deliveries continues extremely tame, despite inducements that have been offered in the shape of modified prices, and spot stock has been taken in very small quantities, although cheaper nearly all along the line at present than for some time past. Stocks here are liberal and the assortment is remarkably good.

Chicago Report.

Scrap.—Trade is very dull. Dealers quote the following buying prices:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$10.00	....
Machinery Cast	7.50	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	5.00	....
Burnt Iron and Grate Bars	4.00	....
Sheet Iron and Hoops	3.00	....
Plow Steel and Breaking Stock	6.00	....
No. 2, such as Shovels, Hoes, &c	4.50	....
Old Boilers—whole (Iron)	6.00	....
" (Iron)—cut in single Sheets and Rings	9.00	....
Old Gas-Pipe and Boiler Tubes	6.00	....
Cast Borings	3.50	....
Turnings	5.00	....
Horseshoes	10.00	....
Copper Bottoms	....	7 ¢
Copper Clips and Heavy	....	8½¢
Heavy Brass	....	7½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2½¢
Zinc	....	2¾¢
Rubber	....	2¾¢

Anthracite.—There is hardly any movement at present. Dealers quote carload lots of 12 net tons as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

UNDER DATE OF JUNE 30 the copartnership heretofore existing between Robert Roger Haydock and Eugene Bissell, under the firm name of Haydock & Bissell, 12 Murray street and 15 Park place, New York, was dissolved by mutual consent. R. R. Haydock retires to assume the position of sales agent of the Bethlehem Iron Company, in charge of their office at 421 Chestnut street, Philadelphia. Mr. Bissell will continue the auction and commission business at the former stand in connection with E. V. N. Bissell and Frank Van Name, under the firm style of E. Bissell, Son & Co. The new firm assume all the assets and liabilities of the old concern.

SPECIALTY MFG. COMPANY is the name of a concern who have recently commenced the manufacture of wringers, clothes washers, step, common and extension ladders, rat traps, lemon squeezers, &c., at Titusville, Pa. The officers of the new company are as follows: L. T. Gorenflo, president; D. J. Whitney, secretary, and R. L. Rice, treasurer. Mr. Gorenflo was connected with the F. F. Adams Company of Erie, Pa., for 20 years, during the last six of which he held the position of superintendent of their factory. Mr. Whitney has also been connected with the F. F. Adams Company for the past six years. The company's factory was started June 1 and we are advised that they are now in full operation.

CONDITION OF THE

Hardware Trade.

THE PAST WEEK, with the turn of the half-year and the national holiday, has naturally had but a limited volume of business, and July opens with the usual midsummer inactivity in trade. For the past few weeks manufacturers have been preparing for the usual shut down for a longer or shorter time in order to make repairs and to put things in shape for future operations. Travelers also are nearly all at home, and merchants generally are refraining from pressing sales. In a week or two it will be feasible to compare the aggregate of the six months' business with that of previous years, and it is hoped that the result will not be altogether unsatisfactory. Little of importance in the matter of prices has developed since our last report, but while the market is not characterized by a strong tone there have been comparatively few open declines. The large trade and manufacturers are feeling the effect of the disturbed financial conditions which prevail, but throughout the country generally a fairly satisfactory business is being done by the smaller trade.

Careful inquiry among retailers, as well as advices from commercial travelers who have recently been in close contact with them, develops the fact that in many parts of the country, in the smaller towns and villages especially, retailers are not feeling the depression which exists in many of the larger centers of trade. Reports indicate that their business during the past half year has been fully up to the average, and while there is some complaint in regard to collections it is evident that many of them are suffering little from this cause. As an illustration we give the following extract from a letter from a representative house in Western New York:

The financial disquietude of the West and in the cities of the East has not as yet reached the country towns of Western New York, and we are living in hopes it will not, as our banks are not speculative banks and have not been obliged to call in their loans, but are very careful in making new loans. Ours being a farming country, is a little depressed on account of the low price of wool and other products, and collections are slow.

Similar advices come to us in the following communication from a Hardware firm in one of the prominent manufacturing cities of Connecticut:

We are fortunate to live and do business in a very conservative and healthy community. Financially, we have as yet felt little of the effects of the monetary disturbance prevailing at the present time. Our manufacturers are all sound and able to carry on their business without outside aid as to money, and up to this time they have all continued to manufacture goods and keep their hands employed. Our merchants have had a very successful season so far, and very little complaint has been heard from them. Taking all together we should hardly know there was a scarcity of money, except from reading the newspapers. Our local banks have funds at their command equal to any demand that may be made upon them for local business. Building is somewhat held back by lack of funds in savings banks, as out-of-town savings banks are not loaning money here so freely as last year. Yet a drive around our little city will show at least 60 new houses being built. If the situation grows no more serious than at the present time our city will feel very little of its effects.

Advices from Chicago.—A period of dullness has set in in Hardware circles, which is perceptible in every establishment. Orders are numerous enough, but they are for very small quantities, indicating that retail merchants are merely purchasing to cover absolute wants. The quietness is felt in all branches of the Hardware trade and affects all kinds of goods. Prices show no material change. Collections are not improving.

Notes on Prices.

Cut Nails.—Many of the mills have already shut down for repairs, and on account of the condition of the market, the demand being moderate and prices far from satisfactory. They will evidently pursue a conservative course and avoid accumulating stocks, and it is not unlikely that they will shut down for a longer period than usual. The quotation of $1.05 for carload lots at mill still represents the market, but has recently been shaded slightly on regular averages, and with more freedom where the specification is especially attractive. The volume of business, however, is moderate, and the market is decidedly sluggish. Small lots of Steel or Iron Nails from store in New York are quoted regularly at $1.30 to $1.35.

Advices from Chicago.—The condition of trade is about the same as was reported last week. Orders are light and specifications are coming in slowly. Prices remain as before at $1.20 to $1.25, Chicago, for factory lots and $1.30 to $1.35 from store for small lots.

Wire Nails.—There is little new to report in this line. The mills, with perhaps one or two exceptions, have shut down for the month, in accordance with the understanding reached a few weeks ago. This, it is hoped by the manufacturers, will have the effect of giving the market a somewhat better tone and will certainly prevent the accumulation of stocks. While during the month little attention will be given to sales or manufacturing, it is expected that the conferences, with a view to reaching some understanding in regard to improving the condition of the market in this line, will be continued, and the opinion is freely expressed by well-informed parties that the course of things during the past year has impressed upon the manufacturers the necessity of doing something to prevent the demoralizing competition which has prevailed. The general quotation

for carload lots at mill is $1.35, but some of the manufacturers refuse to meet this figure. On the other hand, it has been shaded by others in special cases.

Advices from Chicago.—Manufacturers report a fair demand, considering the general dullness of trade Prices are unsettled, with many wild rumors afloat regarding offers which are claimed to have been made. Notwithstanding these rumors sales are being made at rates which could certainly not be obtained if but part of such reports were true. Prices seem to be confined closely to about $1.45 to $1.50, Chicago, for factory lots. The mills are all closed down in the West. The Joliet Mill has shut down in every department. The curtailment of production is expected by manufacturers to advance prices within the next two or three weeks, especially in view of the fact that stocks are reported light in all warehouses. The stocks held by the manufacturers on June 1 were said to have been the lowest reported for five years, and the reports for July 1 are expected to be equally satisfactory. Jobbers quote small lots from stock at $1.55 to $1.60.

Barb Wire.—The Barb-Wire market is inactive and prices unchanged on a basis of $2.45 to $2.50 for Four-Point Galvanized in carload lots at mill.

Advices from Chicago.—Trade from factory is very quiet now, as is usual in July. The factories generally have suspended operations and will stay closed for the next month or so. Carload prices are unchanged at $2.15 for Painted and $2.55 for Galvanized. Small lots from stock are selling at $2.30 and $2.70, respectively.

Polishes.—The following is the price-list and discount sheet on the Polishes manufactured by the Tanite Company, Stroudsburg, Pa. Each case contains 12 tins, and the company announce that they will not sell less than a case of these goods. Terms 60 days, 2 per cent. discount for cash in 10 days, f.o.b. Stroudsburg, Pa.:

	Per gross.
Paste, put up in 1-pound tins	$36.00
Discount, less than 1 gross, 35 per cent.; 1 gross, 40 per cent.; 5 gross, 45 per cent.	
Liquid, put up in ½-pint tins	36.00
Discount, less than 1 gross, 50 per cent.; 1 gross, 55 per cent.; 5 gross, 60 per cent.	
Gray, put up in 1-pound tins	36.00
Discount, less than 1 gross, 45 per cent.; 1 gross, 50 per cent.; 5 gross, 55 per cent.	
Brown, put up in 1-pound tins	36.00
Discount, less than 1 gross, 50 per cent.; 1 gross, 55 per cent.; 5 gross, 60 per cent.	
Dove, put up in 1-pound tins	36.00
Discount, less than 1 gross, 55 per cent.; 1 gross, 60 per cent.; 5 gross, 65 per cent.	

Mangles.—The Eclipse Mangle is put on the market by the Lang Mfg. Company, Racine, Wis. The prices on this Mangle, and also on the company's Family and Domestic Mangles, are given below, and are subject to a discount of 25 per cent.:

Eclipse, 24 inch	$30.50
" 27 "	33.00
Family	22.00
Domestic, 24 inch	35.50

Granite and Agate Iron Ware.—St. Louis Stamping Company and Lalance & Grosjean Mfg. Company announce that beginning July 1 they will allow an extra discount of 10 per cent. on the following articles in Granite and Agate Iron Wares:

	Nos., inclusive.
Lipped Preserving Kettles	14 to 50
" " "	140 to 600
" Sauce Pans	9 to 30
Wash Bowls, Plain & Ringed	24 to 36
Tea Kettles	20 to 100
"	6 to 9
"	31 to 36
"	16½ to 26½
"	302 to 308
"	60 to 100
"	2 to 10
"	600 to 900

Glass.—The Glass factories have shut down for the summer, thus closing the season of 1892-93. Notwithstanding the unfavorable spring weather and later financial uncertainty, it is believed that the average of trade done was better than for the past seasons. Window Plate and Cathedral Glass have suffered more for lack of demand than Window Glass has. No doubt many of the Window-Glass firms would have been obliged to close down for want of funds to pay the operators' wages even if it had not been the annual time for closing the factories. Most of the Window-Glass houses started about September 2 for the season of 1892-93, and have, as a rule, made an uninterrupted run up to July 1, 1893. Probably the output of Glass was the largest in the history of the trade, while it is reported that the stocks at present in the makers' hands are smaller than usual at this season of the year. Prices, as we have stated before, have been sustained largely through the efforts of the National Window Glass Association. Present indications point to larger output during the next fire than during the past, and also to a more active demand for Glass. The Plate-Glass trade shows a little more activity, and the situation is likely to become stronger as stocks decrease. The New York importers of Glass held a meeting last week, at which no change in prices was made. It was decided to make no contracts for the future, and contracts which expired July 1 will not be renewed. The situation in imported Glass is consequently stronger. Prices remain as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—Referring to the following quotations it will be seen that a reduction has been made in the prices paid for some grades of Old Rubber. These are the current prices paid for Old Rubber delivered in New York:

Car Springs, ton lots, ℔ lb.	@	$0.03¼
Rubber Shoes, carloads ℔ lb.	@	.03⅛
Rubber shoes, less than carloads.	@	.03
Large Hose, ℔ ton	@	9.00
White Wringer Rolls, ℔ lb.	@	.04¼
White Syringes, ℔ lb.	@	.05

Old Rags, Paper, Etc.—From the corrected quotations on Old Rags, Paper, &c., it will be noticed that lower prices are named for White and Mixed Rags, on some grades of Paper and on Jute Butts. The following are the current prices paid for Old Rags, Paper, &c., delivered in New York:

No. 1 White Rags	℔ lb	3	@ 3⅛¢
No. 2 White Rags	℔ lb	2	@ 2⅛¢
Mixed Rags	℔ lb		1¼¢
Blues and 3ds	℔ lb		1¼¢

Hemp Twine	℔ lb	2½¢
Manila Rope	℔ lb	2¼¢
Jute Rope	℔ lb	1⅞ @ 2 ¢
Mixed Rope	℔ lb	¾ @ ⅞¢

Trade Notes.

The Raven Stove Polish Company of Chicago have a remarkably fine display of their Stove Polish in one of the large windows of Siegel, Cooper & Co.'s department store on the corner of State and Van Buren streets, in the same city. The entire window, 18 feet high, 9 feet long and 8 feet wide, was set aside for this display, which includes graphite from the Sonora mines in Mexico, to show the material from which Raven Stove Polish is made; packages of Lead Pencils made for the United States Graphite Company of Saginaw, Mich., to illustrate the high character of the same graphite; pails of Raven Polish, as put up for manufacturers; boxes of Raven Polish, as put up for the general trade, built in various fanciful forms, and an automatic female figure polishing a stove with Raven Polish. The whole arrangement is exceedingly creditable to those who originated and completed it, attracting

crowds of people daily by its unusual character.

We are indebted to the Nubian Iron Enamel Company of Cragin, Ill., for a copy of a neat desk calendar for the three months of the year ending September 30. In general shape it conforms to the calendars issued by the company for the previous months of the year, and as may be supposed refers at some length to the merits of Bonnell's Nubian.

Myer & Cooney, Indianapolis, Ind., find their specialty, Rain Water Cut-Offs, in great demand. Their line of Tinware embraces a complete variety, and though their facilities for production have been frequently enlarged and improved, they still are taxed to keep orders promptly filled.

The Tanite Company of Stroudsburg, Pa., have just issued circulars relating to a liquid polish which has been prepared to meet the wants of the trade. It is stated that the polishing paste offered by the company is free from injurious ingredients and is intended for the same purposes as are met by the liquid polish, to the employment of which many in the trade are opposed. Accompanying the descriptive circulars which the company have issued relative to this paste is a price-list and discount sheet on polishes manufactured by the Tanite Company.

I. P. Frink of 551 Pearl street, New York, has recently supplied a number of buildings with Reflectors, designed for use in connection with electric lighting and gas illumination. Prominent among these structures may be mentioned the Gallery of Fine Arts, World's Fair, Chicago; the State House at Columbus, Ohio; the Chicago Art Institute, the Convention Hall at Saratoga, and 35 prominent churches in various parts of the country.

The Newton Machine Tool Works, Philadelphia, Pa., issue a handsome catalogue of their Cold Saw Cutting-Off Machines, showing illustrations of the different machines, together with brief description. The publication, likewise, gives a list of testimonial letters.

The Joseph Dixon Crucible Company, Jersey City, N. J., and 68 Reade street, New York, have two exhibits at the fair. One is of Dixon's American Graphite Pencils, in the northeast gallery of the Manufactures Building, and the other, covering all the other articles manufactured by them, in the northeast gallery of the Mines and Mining Building. The Pencil exhibit occupies a space 10 x 14 feet and consists of a low mahogany table surmounted by a pyramid of velvet, covered with Pencils, arranged in graceful and beautiful designs by an artist employed specially for that purpose, over which stands a rosewood and plate-glass case. The exhibit of general and special Graphite products in the Mines and Mining Building occupies a space 25 x 28 feet. Crucibles, Retorts, Ladles, Stopper Heads and Nozzles, Graphite Boxes. Phosphorus Chargers, Resistance Rods and devices, Incandescent Filiment Forms, and other special goods made of Graphite, are shown in upright cabinets. In a case is shown the development of an electrotype plate, in which process the use of Graphite is an essential. In still another case are shown over 50 varieties of Graphite, such as Graphite for lubricating, stove polish, foundry facings for green, dry or loam castings, core wash, ingot mold wash, shot and powder glazing, electrotypers, gilders' use, hatters' use, rubber packings, piano and organ actions, "potleading" yachts, for crucibles, lead pencils, paint pigment, lubricants, &c. There are also shown samples of Graphite from all the principal sources from which that article is obtained. One very fine sample from the Island of Ceylon weighs nearly 300 pounds.

Wisconsin Refrigerator Company, Eau Claire, Wis., advise us that they have been unable to keep up with orders, and are contemplating large improvements in their plant for next season.

Ingersoll Mfg. Company of Lansing, Mich., have brought out a lamp-stove which they term the Magic room heater. It consists of a square metallic table with four legs. The lamp is placed in a frame a short distance from the floor and the heat passes through what is termed the "heat battery" at the top, which is composed of a great number of hot air pipes or ducts. Air currents are drawn through the battery, heated and discharged into the room. It is claimed that the stove will heat a room 16 x 16 feet in cold weather, with the consumption of one gallon of oil in 12 to 15 hours. The size of the stove is 10 x 10 inches and 30 inches high. When not in use as a stove it forms an ornamental table or stand.

F. H. Rice, senior member of the firm of Rice & Miller, hardware merchants of Elkland, Pa., has accepted a position as traveling salesman of the Eureka Range Company, with headquarters at Mansfield. Mr. Miller will continue the business at the old stand.

Matthai, Ingram & Co. of Baltimore, Md., have nearly completed the repairs to their factory buildings rendered necessary by their late fire, and have made some large additions. The fire started in the retinning department and extended to their three story factory building. They are now building a new retinning shop, 40 x 180 feet, which is much larger than the old one. This new building will be absolutely fire proof, it being constructed of brick, with iron girders, roof, window frames and shutters, and there being no wood work whatever about it. The sheet and black goods department will be contained in a new four-story brick building, 70 x 140 feet, and forming an ell to this building is a new four-story building, 40 x 135, to be used as a tinning shop. A galvanizing plant will occupy a building which was formerly located on the site where the retinning shop is being built, but which has been moved to an adjoining lot recently purchased. With these additions and extensions the firm's capacity for production of their goods will be considerably increased in all departments, and they will be enabled to manufacture a line of goods which they have for some time had under contemplation.

Gummey's Anti Pin Hole Bright Tin Plate is the subject of an advertisement elsewhere by Gummey, Spering & Co. of Philadelphia. They describe this plate as the only absolutely anti-pin hole plate ever made. They say that experience proves its success, and that it is guaranteed in full. This will be welcome news to those who have searched for a plate that would not pin hole, which complaint has been so common heretofore and has caused so much trouble and expense in the manufacture of a certain class of goods.

P. J. Conroy & Co. of Paschall, Philadelphia, manufacturers of Refrigerator fittings, have added to their line a Refrigerator and Cooler Faucet, and a Refrigerator Door Fastener, especially suitable for large doors.

NEW JERSEY LAMP & BRONZE WORKS, New Brunswick, N. J., and 91 Duane street, New York: Lamps, Stove Figures, Urns, &c. Two handsomely illustrated catalogues are devoted to these goods, of which there are a large number of designs, many of them in colors. A specialty is made of Clock Figures, of which there are a large number shown. The catalogues are artistic in design and arrangement, and indicate time and labor spent in compiling them.

OIL WELL SUPPLY COMPANY, Pittsburgh and Oil City, Pa. and New York: Artesian Well Supplies. This their second edition contains 374 pages, while their first catalogue had but 160 pages. It illustrates a large line of goods related to the industry, including prices and descriptions. The manufacturers state that they have ten separate, fully equipped manufactories, in which nearly 3000 people are employed, so that they can themselves make anything required to equip, drill and operate Artesian Wells for Oil, Gas, Water or Minerals. The catalogue is comprehensive, well printed, and substantially bound in cloth.

STUDEBAKER BROS. MFG. COMPANY, South Bend, Ind.: Studebaker Souvenir. The book is handsomely illustrated, showing Vehicles in colors, also views of the interior and exterior of their works. It is bound in cream colored paper, with gold letters. The work will be interesting to those handling this line of goods.

MILLER LOCK COMPANY, Frankford, Philadelphia, Pa.: The Jackson Lock Cylinder. The catalogue illustrates the application of the Cylinder to a variety of Locks, including Rim and Mortise Latches, Front and Vestibule Door Sets, Safe Deposit Locks, Post Office Lock Boxes, Cabinet, Drawer, Cupboard and Chest Locks, &c. The manufacturers claim the Lock to be non-pickable.

KOHLER, HAYSSEN & STEHN MFG. COMPANY, Sheboygan, Wis.: Illustrated catalogue of Flint Enameled Stamped Steel Ware, Cast Iron Enameled Stove Ware, Reservoirs, Maslin Kettles, Cuspidors. Sinks, Drip Trays, Enameled Iron Bathtubs, Evaporating Dishes, Caldrons for Chemical uses, and Lawn Vases and Settees. The catalogue comprises 46 pages, containing full price-lists as well as descriptive matter relating to the various goods.

It Is Reported—

That J. W. Estabrook recently purchased the Hardware stock of A. C. Weeks, Marlboro, Mass.

That Stuhr Hardware Company's store at Minden, Iowa, was destroyed by fire on the 22d ult.

That Erickson Bros., Hardware dealers, Watson, Minn., have been succeeded by G. A Anderson.

That Stearns Bros., dealers in Hardware and Implements, New Richland, Minn., have been succeeded by Stearns & Sorgen.

That Prescott, Mars & Co., dealers in Hardware, &c., Virginia, Minn., were burned out recently. Loss, $15,000; insurance, $7,600.

That Robert Barry has bought the Stove and Tinware business formerly conducted by F. D. Draper, Norwood, Mass.

That A. M. Bryant, Hardware dealer, Buckley, Wash., has sold out his business.

That J. A. Bunnell, dealer in Hardware, Implements, &c., Clyman, Wis., has sold out to John T. Collins.

The growth of European armies in the last 23 years is strikingly set forth in the following table of comparison of the armies of Europe on a war footing, in 1869 and in 1892, recently furnished to the New York *Herald* by its Paris correspondent:

	1869.	1892.
France	1,350,000	4,350,000
Germany	1,300,000	5,000,000
Russia	1,100,000	4,000,000
Austria	750,000	1,900,000
Italy	750,000	2,236,000
England	450,000	602,000
Spain	450,000	800,000
Turkey	320,000	1,150,000
Switzerland	150,000	489,000
Belgium	95,000	258,000
Portugal	70,000	154,000
Holland	45,000	185,000
Denmark	45,000	91,000
Montenegro	40,000	55,000
Greece	35,000	180,000
Roumania	38,000	280,000
Servia	25,000	180,000
Totals	6,958,000	22,248,000

It will thus be seen that the numbers have more than tripled since the time of the Franco-German war.

Current Hardware Prices.

JULY 7, 1893.

Note.—The quotations given below represent the Current Hardware Prices which prevail in the market at large. They are not given as manufacturers' prices, and manufacturers should not be held responsible for them. In cases where goods are quoted at lower figures than the manufacturers name, it is not stated that the manufacturers are selling at the prices quoted, but simply that the goods are being sold, perhaps by the manufacturers, perhaps by the jobbers at the figures named.

The character @ is used to indicate a range of price; thus discount 50&10@50&10&5 % signifies that the goods in question are sold at prices ranging from discount 50 and 10 % to discount 50 and 10 and 5 %.

News and Notes.

Mining is depressed in Scotland, the North of England and Yorkshire, a large number of mines being quite idle, and many collieries working short time.

In view of the threatened dearth of fodder in Europe, the French Academy of Sciences recommends utilizing the leaves of the grape vine for this purpose. Cattle eat them, either fresh or dry, with avidity, and they are stated to be excellent food. It is calculated that French vineyards can provide in this manner food equal to more than 800,000 tons of hay.

The Italian Government has approved of a project for the enlargement of the port and construction of new docks at Palermo, which will make the Sicilian capital one of the most important seaports of the Mediterranean.

A "Society for Promotion of the Atmospheric Purity of Cleveland" is an association which has been formed to suppress the smoke nuisance in that city.

The closing down of all the Chilian mines may result from the fall in price of silver. The situation has caused much excitement among those interested in the mining industry of Chili.

Returns from the Bureau of Statistics show that imports of merchandise into the United States during the year ended May 31, 1893, exceeded exports to foreign countries by $87,627,444.

Chili has recently received her newest and finest cruiser, the "Capitan Prat." The vessel was built in France, and is of 6900 tons displacement. She carries four 9½-inch and eight 4¾-inch Cavet guns and bears a water-line belt of 11¾ inches of armor, while her ascertained speed is 19 knots an hour.

The "Campania" in her last westward voyage broke the record for the best day's run, accomplishing 548 miles in 24 hours.

Insurance companies report unusual difficulty in collecting balances, and July statements promise to exhibit an enormous amount of premiums uncollected. Fire insurance corporations thus find their margin of cash in hand for the payment of losses uncomfortably narrow.

United States Consul General Wallace of Melbourne reports the great success of Australian hard woods for street paving. The "jarrah" and "karri," both indigenous to Australia, are used in the most frequented roadways of the principal cities, and are found to give the best results as paving material.

The prolonged drought in Europe has at last broken up, and much-needed rain is reported to have fallen. Its effects, however, will be serious on the year's crop returns of Great Britain, Germany, Austria, Italy and France; in all of which countries scarcity in many kinds of agricultural produce has occurred.

The sardine fishery of Brittany employs 2500 boats manned by 15,000 men. Along the coast are established 150 canning factories, which give work to about 12,000 persons, principally women, the total annual expenditure for labor, material, &c., reaching nearly $4,000,000.

Consul-General Hess of Constantinople is of the opinion that a favorable opportunity for the introduction of improved American milling machinery into Turkey is offered by the recent abolition of the 8 per cent. import duty hitherto levied on wheat and flour at Turkish ports.

A Genoese firm are reported to have collected and forwarded to Rio de Janeiro 38,000 Italian and Spanish emigrants during the past year, under a contract with the Brazilian Government.

A Washington dispatch states that the Ordnance Department of the Navy has prepared advertisements for nearly 1,500,000 pounds of steel forgings to be used in the construction of 4, 5, 8 and 12 inch rifled guns.

The interest created in our new men-of-war has stimulated the formation of further battalions of naval militia. Several States are now contemplating their establishment. At present over 2000 officers and men are enrolled.

The Austrian Government are content to pay the piper to a pretty tune for the purpose of "encouraging home industries." Thirty-seven dollars and ninety-two cents per ton for steel rails is the price which they have agreed upon, and to get even this they have had to place the whole of their requirements with native works for the next five years, meaning from 100,000 to 150,000 tons.

China protests vigorously against the enforcement of the Geary act as derogatory to her dignity and disturbing to the friendly relations existing with the United States. The Government of the Empire has officially requested a reconsideration of the obnoxious law.

A movement is on foot in England to have all iron and steel manufactured in that country regularly stamped as of British manufacture. The proposal is stated to have been heartily taken up by the British Iron Trade Association, and some hundreds of manufacturers have intimated their willingness to so mark their goods whenever possible. The idea is to obviate the mistakes and loss arising in the foreign trade from imitation of trade-marks by foreign competitors.

An Engineering Exchange has been established in London, in the premises of the London Shipping Exchange, Billiter street. The exchange has writing, reading and smoking rooms, refreshment and dining rooms, board and committee rooms, lavatories, exchange telegraph tape, telephones, and all conveniences. The general membership exceeds 1000. 'Change is held daily from 3.30 to 4 p.m. Engineers visiting London can obtain an order to visit the exchange from the secretary, Mr. A. T. Salisbury-Jones, 33 Old Broad street, E.C., or from a member of the committee.

Sir Thomas Sutherland, M. P., chairman of the P. & O. Company, at the half-yearly meeting of that steamship corporation in London recently, said that an analysis of the returns of all the great British shipping companies showed a melancholy record of bad trade and inadequate profits. The depression in shipping stocks is, however, more plainly exemplified by the Stock Exchange quotations, from which it appears that the average depreciation of these stocks is not less than 50 per cent.

We are indebted to Daniel P. Holmes, Norwich, N. Y., for a warm-air furnace estimate book that he has just published. The volume, 7½ x 5½ inches in size, is bound in stiff covers, and contains a set of 50 furnace estimate blanks that will be appreciated by the trade. Every two facing pages contain the blanks for the estimate. The first page gives a line for address and date of contract, the amount at which it is taken, together with spaces for cubic contents of the house. Then comes the furnace and the list of registers, borders, &c. Tin pipe, boxes, heads, collars, dampers, thimbles and all the other necessary furnace fittings are given. At the end of the second page are miscellaneous items, such as asbestos coverings, cold-air boxes, &c., together with space for the work, railway fare, board bills and such items. The whole thing is very compactly arranged and is a permanent record of the different jobs.

LABOR EXCHANGE.

Notices under this heading of reasonable length are inserted free of charge. Only those relating to employment are admitted. Write distinctly on one side of paper only, and do not use postal cards.

HELP WANTED.

At once, a good CORNICE MAKER; one who can estimate from plans and make himself generally useful. "H., S. & M.," office of *The Metal Worker*, 96-102 Reade street, New York City. July 8

A good all round PLUMBER who understands and can do steam and hot-water fitting; must have first-class reference; a permanent place for a reliable man; state wages expected. Harry C. Worrell, Riverton, N. J. July 8

A first-class PLUMBER can obtain steady employment if sober and reliable; one that understands steam and gas-fitting preferred. J. V. Vrooman's Sons, Schenectady, N. Y. July 8

First-class HOT-AIR FURNACE MAN to take charge of our furnace department; must be competent in handling help, a good mechanic and a pusher. A. J. Lindemann & Hoverson Company, 223 Reed street, Milwaukee, Wis. July 8

STOVE SALESMEN for Iowa, Illinois and Wisconsin; Commission. "Stoves," office of *The Metal Worker*, 59 Dearborn street, Chicago, Ill. July 8

Young man to assist in the heating department of an established firm; must be accustomed to hot air furnace, range and tin shop work, and be experienced in estimating, especially from plans and in getting work ready for shipment; one previously employed in this capacity preferred; give explicit particulars. "Thoroughly Reliable," care of *The Metal Worker*, 96-102 Reade street, New York City. July 8

A large tinware manufacturing house wants a man thoroughly posted in that line to take charge of their shipping department, which includes the getting out and packing of orders; one who has held a similar position preferred; to the right party this is an excellent opening. Address, with references, "Tinware," office of *The Metal Worker*, 96-102 Reade street, New York City. July 1

A first-class COPPERSMITH who thoroughly understands making hotel kitchen utensils. "W. L. C.," office of *The Metal Worker*, Bank of Commerce Building, St. Louis, Mo. July 1

A first-class HOT-WATER FITTER; one who can do general jobbing on tin and sheet-iron work; good pay; steady work. C. K. & C. W. Labaree, Bellows Falls, Vt. July 1

Experienced man to take charge of steam heating and plumbing department. Canfield Stove Company, Rondout, N. Y. July 1

A man thoroughly acquainted with the trade to travel, handling our self-pouring oil can. Paine, Diehl & Co., Philadelphia, Pa. July 1

SITUATIONS WANTED.

By a thoroughly PRACTICAL MECHANIC; understands house heating by steam, hot water and hot-air furnaces; can draft patterns for all kinds of sheet metal work and do work from plans. J. P. Lisk, Box 391, Bridgeport, Conn. July 8

A young man wishes a position in city or country as first-class tinsmith, roofer, tin and sheet-iron worker, general jobber; knows how to repair stoves, ranges and heaters, also a little plumbing. S. Richmond, 31 Monroe street, New York City. July 8

TRAVELING SALESMAN who has been with a tin-plate stamping house for the past 13 years and has taken in all the principal cities in the United States and Canada, desires a situation, either on salary or commission. H. H. Witte, 84 North Washington avenue, Columbus, Ohio. July 8

By an all-round SHEET METAL WORKER, CORNICE and FURNACE MAN of 18 years' experience; can take charge of shop and act as foreman, and works from planes; would be pleased to engage with some firm west of Missouri River by July 10. James Thomas, Denver, Col. July 8

By a TINSMITH and ROOFER, city or country. Geo. McGinis, 197 Mulberry street, New York. July 8

By a TINSMITH, steady job at low wages. H. Marcus, care of Mr. Shipman, 47 Lewis street, New York. July 8

SUPERINTENDENT of stove foundry desires position; 11 years' experience with first-class concern; West preferred; first-class reference. "Superintendent," Box 78, office of *The Metal Worker*, 96-102 Reade street, New York City. July 8

By a good TINSMITH with 12 years' experience—three years in this country—at a salary of $2 a day. S. Hyman, 201 Forsyth street, New York. July 8

As FOREMAN by practical tinner of 16 years' experience at roofing, slating, cornice and furnace work; best of reference; small city in Indiana or Illinois preferred. "O. L. R.," 303½ North Thirteenth street, Terre Haute, Ind. July 8

By a TINNER and CORNICE MAKER who can cut patterns and work at hammering and stove work. Chas. J. Lindel, Tuscumbia, Ala. July 8

By a first-class PLUMBER, in city or country; best of references given. Robert Smith, 964 Third avenue, New York City. July 8

A young man, age 26, with 12 years' experience in tin, sheet-iron and cornice work and roofing, understands plumbing and gas fitting and does all kinds of general jobbing, speaks English and German, desires a steady position. H. Altman, 83 Sheriff street, New York City. July 8

By a young man, a steady situation as PLUMBER, to work under instruction; graduate of New York Trades School; has had considerable experience at trade; good reference. P. O. Box 39, Moundsville, W. Va. July 8

TINSMITH and ROOFER, and for other general jobbing. Jacob Samuals, care of Mr. Dzalka, 110 Clinton street, New York City. July 8

By a STOVE IRON PATTERN FITTER; several years' experience. "J. L.," office of *The Metal Worker*, 96-102 Reade street, New York City. July 8

CORNICE and SKYLIGHT MAKER, CUTTER and DRAFTSMAN; a thorough mechanic in all branches; capable of taking charge of shop; has experience as foreman; understands handling help to best advantage and work; would like a steady position. "C. D. F.," office of *The Metal Worker*, 96-102 Reade street, New York City. July 8

As PLUMBER by a sober and industrious young man; city or country. Henry J. Schlag, 420 East Fifty-ninth street, New York City. July 8

Position in good cornice shop to assist in cutting and work under instruction; state wages to a steady man. Chapman & Chapman, Hutchinson, Kas. July 8

By a TIN and SHEET-IRON WORKER with ten years' experience; city or country; New York preferred; sober and industrious. "A. G.," care of B. Abel, 189 Christie street, New York. July 8

SHEET METAL PATTERN CUTTER desires position in a first-class cornice shop; thoroughly competent to take entire charge, New York or vicinity preferred. "Pattern Cutter," office of *The Metal Worker*, 96-102 Reade street, New York City. July 8

BRASS FINISHER, soft and hard solderer; city or country. Louis Fried, 124 Lewis street, New York. July 8

SALESMAN would like to engage with house carrying a full line of tinners' supplies to cover New England States; can dispose of large amount of goods, as previous records will show. "D.," 575 Hudson street, New York. July 1

A first-class TIN and SHEET IRON WORKER, has been at the trade for 20 years doing furnace, stove, roofing, pumps, iron pipe and general jobbing, wants a steady situation; temperate and reliable. F. Mead, Long Island City, N. Y. July 1

STOVE SALESMAN that is acquainted with the trade in Missouri to represent a good line of goods that is made near that territory and known in that State; give reference and state salary wanted. "R.," office of *The Metal Worker*, 22-24 Pickering Building, Cincinnati, Ohio. July 1

By a young man of 31, married, in retail stove and tinware store; five years' experience as salesman and buyer; A1 reference. "Stoves," office of *The Metal Worker*, 96-102 Reade street, New York City. July 1

By a sober and industrious TINNER and CORNICE MAKER, who also understands plumbing; can go to work in 30 days after notified; $2.50 a day desired, with steady work for a year. Chapman & Chapman, Hutchinson, Kan. July 1

PLUMBER, practical, and first-class mechanic, desires a position as FOREMAN, or would work journey work; 18 years' experience at trade; wages must be first class; please state wages. James Emmett, care of Usher, 427 E. 114th street, New York City. July 1

By a practical TINSMITH with 16 years' experience in all branches of the trade; can do furnace, heater, range, roofing and pump work and general jobbing; fair knowledge of plumbing; capable of taking charge of shop; steady position year round; state terms; German; married. "William," care H. Rathjen, 13 Columbia Heights, Brooklyn, N. Y July 1

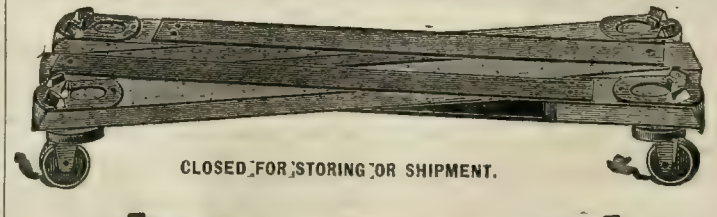
A young man (28), thoroughly conversant with steam and hot-water heating, capable of estimating, drawing plans, erecting or superintending same, is desirous of a position with an establishment where industry will be appreciated. "Hot-Water Engineer," office of *The Metal Worker*, 96-102 Reade street, New York City. July 1

An ARTIST wishes work painting machinery or anything; wages very low; understands oil, water colors and varnish. "J. P.," Box 87, Medina, Ohio. July 1

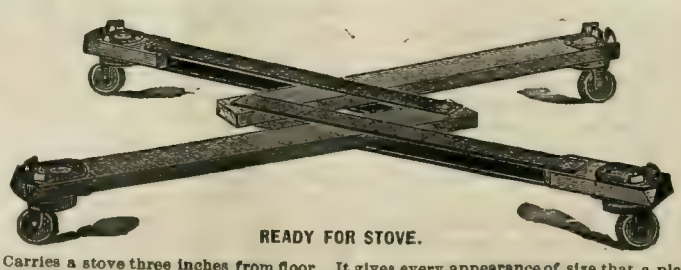
By a first-class TIN and SHEET-IRON WORKER of 15 years' experience and a hustler; strictly sober and reliable; understands all kinds of work; city or country; has had charge of men. "Tinsmith," P. O. Box 37, Taunton, Mass. July 1

Situation as FOREMAN or JOURNEYMAN BRASS MOLDER; first class on engineers' electric, hydraulic and general brass work, heavy or light; also on church, plantation and other bells; well up in the mixing and melting of any kind of metals and general details of a brass foundry; location no object. H. W. West, 231 Brush street, Detroit, Mich. July 1

THE IMPROVED **LOCK FRAME STOVE TRUCK.**



CLOSED FOR STORING OR SHIPMENT.



READY FOR STOVE.

FOR SALE BY THE **Stove and Hardware Trade.**

SEND FOR CIRCULAR.

Carries a stove three inches from floor. It gives every appearance of size that a platform does and holds stove secure and solid without clamps, yokes, bolts or other useless contrivances, so that

ONE MAN CAN HANDLE ANY STOVE WITH EASE.

Manufactured by RANDALL & WARD, LeRoy, N. Y.

THE METAL WORKER.

NEW YORK AND CHICAGO.

Saturday, July 15, 1893.

Wind-Proof Houses.

The recent disastrous cyclones that have been devastating towns and agricultural sections in the Western States point clearly to the need of a much more secure system of building for the cyclone districts—a system in which sheet metal will probably occupy a prominent place among materials employed for the purpose. At present, and probably for a long time to come, wood must be relied upon for frame work, but for the outside, as well as for the roof, sheet metal as a covering for a truly wind-proof house possesses advantages found in no other material. A wind-proof house is one that can neither be blown down nor have its windows blown in by any wind generated in a natural way. It might have been said, also, one that cannot be blown upward by any natural wind, since accounts of the way buildings are destroyed by the cyclones indicate that many of them are lifted bodily and carried a considerable distance from their foundations.

Wind Pressure.

In order to make the wind press down instead of lift up a building, the sides of the structure should be inclined inward from the bottom upward, as in the Egyptian style of architecture, of which the Pyramids may be taken as an extreme example and the Tombs Building, in New York City, an example of less pronounced application of this principle. A proper amount of inclination would cause the wind to press a building down upon its foundations with greater force than its lifting power. Such a building, having a frame of strength sufficient to withstand the lateral pressure of a cyclone, anchored so that it cannot be slidden off its foundation, while at the same time carrying a continuous covering of sheet metal and provided with stout sash, glazed with small panes of glass, could be made to withstand the force of any cyclone. Of course, the designing of such a building would introduce some novel problems for the consideration of architects, and which would include modifications in methods of heating, ventilation and plumbing; but there can be no doubt that if the attempt was made to construct frame buildings that would safely withstand a wind pressure of, say, 80 pounds per square foot, which is probably as great as is exerted by any natural wind, the desired result could be obtained without any notable difficulty and without extravagant cost.

Absence of Shipping Directions.

Our attention is called to the frequency with which merchants neglect to accompany mail orders for goods with explicit shipping directions. Orders of this kind are often hurriedly written, and, as the merchant has been buying goods from the same firm for years, he has no thought but that its members are familiar with the route by which his goods are shipped; or he may add, "ship same as last." This is probably more annoying than if no shipping directions were given, as it indicates that the merchant has a decided preference as to the route by which the goods are to be shipped, and yet gives no specific directions on this point. The shipping clerk is obliged to search through perhaps six months' business to find how the merchant's last order was shipped, and at a time when he can ill afford to give the attention required. Again, the clerk is apt to have no intimation of how goods are to be shipped until the goods packed ready for shipment are turned over to him for making out the bill of lading. Perhaps 50 or 100 other bills of goods are to be gotten off the same day, so the one entailing the extra amount of labor is laid aside until he has more time. The merchant, in such a case, is displeased because the goods are not promptly shipped. Very frequently there are two stations of the same name in the same State, in which case it would be an advantage to have the county mentioned. In other instances, where goods are ordered by a customer living at a certain post office address whose shipping point is elsewhere, according to the guide used by the shipping clerk, the goods would be shipped to a certain railroad station. The customer, however, might prefer, on account of the better condition of roads or for other reasons, to have the goods shipped to a station other than that mentioned in the shipping guide.

A Good Suggestion.

It is suggested by a large wholesale concern in Philadelphia, in connection with this subject, that it would be an excellent idea for customers in every instance to put on their letter heads the name of the city, county and the State in which they live; and also, if they desire goods shipped to a certain point to have this, too, printed on the letter heads. They state that they occasionally receive letters from customers at the top of whose letter heads are printed the names of the railroads on which they are located, all of which is a decided advantage to the house shipping the goods, saving the annoyance of having goods go to a wrong town, and also saving considerable time in looking up shipping directions. It would be still better if merchants would have order blanks printed with ink that would copy in a letter book, and use copying ink in writing orders, so that a complete record of each order could be found at any time by referring to the letter book. Orders given to traveling men, as well as those sent by mail direct to the house, should be made out on an order blank and copied. At the head of the order blank should be printed the name of the town and county, the railroad or boat route by which the goods are to be sent, and, if by boat, whether the goods are to be insured or not. The terms upon which the merchant wishes to purchase the goods should also be mentioned. All these directions should be given on each order, so that each order will be understood by itself without the necessity of referring to a previous one. The goods ordered should be designated by the catalogue number, or, if no number is given, the size, quality and price of the article should be mentioned. In ordering special goods it is well to insure prompt shipment by adding the word "preferred," "or similar," thus allowing the jobber or manufacturer to substitute such goods as he may, in his judgment, think will be acceptable to the merchant. In a word, the shipping directions and order for the goods should be so plainly given that they cannot be misunderstood.

Savings Banks and Tight Money.

A homily might be written just now on the evils of savings banks. Here are these supposedly beneficent institutions, which encourage thrift among working people, suddenly locking up immense amounts of currency to enable them to withstand "runs" from their depositors and thus causing money to be tighter than ever in the towns in which savings banks are located. They have become very numerous throughout the country, penetrating even rural districts, but are of course strongest in manufacturing towns. In ordinary times they add considerably to the banking capital of the community, enabling manufactur-

ers and business men to enlarge their operations, and perhaps extend them more than they would if money was more difficult to get. At a time like this, however, when accommodations are urgently needed, loans are all called in, and a large share of the available cash of the community locked up for days that may be dangerous, or weeks that may be fatal, to business life. It is unfortunate, but it cannot be helped, and savings banks are not to be condemned for this occasional eccentricity in their usually benignant career.

Electricity vs. Gas.

One of the most interesting contributions to the much vexed question of the competition between gas and electricity was contained in a paper read at the last annual meeting of the Ohio Gas Light Association by Joseph Gwynn. Mr. Gwynn told his fellow gasmen that from investigations he had made into the business of 200 gas and electric light companies he was satisfied that electricity was advancing with unparalleled rapidity in all directions. Gasmen could not shut their eyes to the fact that it had grown more rapidly than the gas business in the past decade, and that a still greater advancement was to be expected in the immediate future, although, ultimately, it might be somewhat checked as the novelty wears off. To demonstrate the growth of the arc-lighting business, it was shown that in 1881 only about 1,000,000 carbons were manufactured, whereas to-day there are upward of 145,000,000 carbons being made and sold annually, showing an average yearly increase of over 12 per cent for the past 12 years. The effect of this growth of lighting by electricity on gas lighting is very noticeable. The following are Mr. Gwynn's words: "To-day, out of over 928 gas companies in the United States, we find of that number only 435 have contracts for street lighting, and 493 have lost the street lighting business entirely, which has been displaced by arc and some few incandescent lights. While, on the other hand, a great many of the gas companies who still do street lighting, do only a limited business in this line, as street lighting by gas is being gradually displaced by electricity and will eventually be a thing of the past." The incandescent lighting business has also advanced enormously, and it last year showed a net increase over gas business of 93 per cent. The use of electric motors for power purposes has also grown in much larger proportion than the use of gas engines in recent years, and the power supplied by this means is doubling itself each year. "The continued improvements," said Mr. Gwynn, "which are many and great in electrical appliances, will continue to make the electric business more simple and reliable, and will still hasten its progress rapidly on for some years to come." In concluding the speaker advised gas companies for the salvation of their business to stand firm and push their business with all the vitality they possess; and to strive to make as good quality of gas as is possible, at a minimum cost, selling it at the lowest price possible to give a fair return on the capital invested. He also urged them to pay special attention to the gas heating and cooking business, this being an almost unlimited field for gas companies, and one that is not likely to be disturbed in the near future by their competitors—the electric light companies. Mr. Gwynn's conclusions have been dissented from by a number of gas authorities, who bring forward the question of cost to the public, one gas journal asserting that the electric light is more costly than gas to the consumer in nine cities out of ten in which it is used, while in the tenth it is probable that the electric light companies are run at a loss. There is at present no indication that the electric current can be more cheaply generated than is the case now; but that is among the possibilities of the future, and when this end is attained the gas companies will surely have to look more to the heating business than to lighting for return from their capital.

How Jones Got an Order.

BY L. A. N.

Many years ago there dwelt in a not far distant town, noted for the generally moral and religious tone of its society, a very industrious, but decidedly unorthodox tinsmith whom we will call Jones. He was so industrious and so unorthodox that, as he never voluntarily entered a church or a religious assembly, he preferred to put in his time on Sundays working steadily in his shop, rather than to rest or go fishing, the, to him, only remaining alternatives. Closing the doors and the wooden shutters of the front windows of his shop he worked diligently while his church-going neighbors were spending their hours in their accustomed devotions.

It so chanced that he obtained a job requiring considerable hammering, the sound of which, as his fellow citizens passed his shop to and from church on Sunday, gave offence. The next day, Monday, he was waited upon at his shop by a self-appointed committee of church goers, who remonstrated with him, and not only pointed out to him the wickedness of his conduct, but described to him a place appointed for sinners, enforcing their arguments with frequent citations of the scriptural command to keep the Sabbath holy and to do no work on that sacred day of rest and worship. To their surprise Jones, who could hold his end in an argument pretty well, and was known to be rather fond of arguing, meekly listened to what his protesting townsmen had to say, and after they had concluded shook hands all around, promising that he would change his course of conduct on the Sabbath in deference to his neighbors' wishes, whereupon they departed much gratified with the result of their interview.

A worthy deacon, in the course of the week, dropped in upon Jones with an order for quite a profitable job, that but for Jones's apparently penitent and hopeful state of mind would certainly have gone to his principal competitor, Smith, who was in the odor of sanctity in the community though he was not nearly so good a tinsmith.

The next Sunday the sound of Jones' hammer was not heard; but conspicuously displayed upon the outside of one of his front window shutters was the following inscription:

"Six days shalt thou labor and do all thy hammering; but the seventh day thou shalt not hammer; thou shalt put in the time soldering, which cannot be heard in the street by thy son, nor thy daughter, thy man servant nor thy maid servant, nor thy cattle, nor by the pious neighbors who pass thy gates."

Exodus XX, 9, 10, Jones' version.

The deacon would have gladly withdrawn his order after reading Jones' version, but Jones had been cute enough to begin the work, and he held the deacon to his contract.

"The Metal Worker" at the World's Fair.

Doubtless a large class among the readers of *The Metal Worker* will visit the World's Columbian Exposition at Chicago during its progress, and at the same time will be glad to know what is going on in their respective branches of trade, as chronicled in the paper from week to week. With a view to rendering reference to its pages an easy matter on the part of visitors, we have arranged with concerns in some of the leading lines covered by *The Metal Worker* to place it on file at their headquarters on the Fair grounds.

Among such firms may be mentioned:

Peck Brothers & Co., Manufactures Building, Section N, Block 4.

Michigan Stove Company, Section O, No. 77.

Magee Furnace Company, Section O, No. 73.

A New Form of Lightning Rod.

A correspondent of *Engineering* states that an accident which took place a short time ago in one of the large Silesian foundries, and which almost proved of disastrous consequences, has induced the owners of the Carls Works in Bunzlau, Silesia, Germany, to make a rather ingenious invention, to which public attention ought to be turned, the question being of importance.

Some time ago the heavy iron bar at the upper end of the lightning conductor of one of the high chimneys in the foundry fell from its considerable hight and caused great damage. The reason was that the vapors escaping from the mouth of the chimney had completely destroyed the lower part of the iron bar. In another case, where the bar was of copper, the lower part became completely oxidized, and the bar bent over and fell. Owing to the ever-varying composition of the coal, containing, for instance, greater or smaller quantities of pyrites, and developing therefrom sulphurous acid by combustion, there must always be danger of complete oxidation and falling down of the lightning bar. The question is now, how to stop this inconvenience?

The Carls Works, Bunzlau, in Silesia, Germany, have met the case in the following ingenious way: The metal bar, being, as a rule, about 4 feet in length and 1 inch in diameter, is surrounded or inclosed by a system of glass tubes of a special form. The interval between metal and glass is filled up by a special kind of cement. The upper end of the highest tube is covered hermetically by a small conical glass, allowing only the platinum point of the bar to project.

The advantage of the construction is obvious. The glass is not susceptible to atmospheric or chemical influence. But there is still a second point worthy of consideration. As a matter of fact, any metal will lose more or less its quality of conducting electricity by oxidation of even only its surface. Thus in time the whole lightning conductor may become useless. To prevent even the slightest oxidation, the above apparatus is suitable.

STEAM AND HOT WATER.

One-Pipe Steam Connections.

BY HELIOS.

Fig. 1 shows connection for one-pipe work from main steam pipe to riser that supplies steam to radiation on upper floors, with drip connection from bottom of riser and drip pipe connected into side of main steam pipe. The branch from the main steam pipe is taken from the top and drips in the direction shown by arrows, if the branch pipe is over 4 feet long; if less than 4 feet it can be level. This connection is used where the branch pipe is long and relieves it of all condensation. It can be used any length. The drip pipe is taken from the bottom of the riser and is usually about two sizes smaller than the steam supply. This drip is connected into the side of the return main when the main return is below the water line.

Fig. 2 shows connection for one-pipe work from main steam pipe to riser that supplies steam to upper floor, with drip connection from bottom of riser. This connection is made the same as in Fig. 1, only the drip is connected into the top of the main return pipe. This connection is used where the main return pipe is above the water line of boiler. In all one-pipe steam work the best results are obtained by having all returns above the water line dropping down to the return connection at the boiler. By having the return above the water line there is no water in the return mains, the boiler will make steam very much quicker and a circulation will be obtained throughout the apparatus in a short time, and if the fire is low in the morning steam can be had in a short time. But if the returns are below the water line and the fire is low, it will take some time to raise steam as the returns are feeding cold water to the boiler, and it will take a much stronger fire and longer time to produce a perfect circulation throughout the radiation.

Fig. 3 shows one-pipe connection to riser from the main steam pipe, with branch pipe connected to under side of main steam pipe and valve in main rising pipe. This connection is used in any place where there are a number of rising pipes supplying steam to radiation on upper floors. The branch supply pipe is taken from the bottom of the main steam to allow the main steam pipe to be run as near the ceiling as possible and to allow room to place the valve in the riser below the floor. By taking the branch pipe from the bottom of the main steam pipe all condensation in the main steam pipe is dripped into the returns at each connection. By placing a valve in the rising pipe repairs can be made to the piping on radiation without interfering with the working of the apparatus, and if the valve is closed it allows the condensation from the main to drip into the return pipe.

Fig. 4, shows one-pipe connection from the main steam pipe with branch pipe taken from the bottom of main steam pipe and connected to riser. This connection should always be made where the main steam pipe is reduced in size, as it removes all condensation from the main steam pipe, which insures a perfect working apparatus and free from noise.

Fig. 5, shows one-pipe connection to a radiator on the second floor connected to the riser, also riser connection to main steam pipe. The tee in the main steam pipe is set at an angle of 45°. A short pipe is run from it and a 45° elbow is screwed on the end which will stand plumb to receive the riser. A tee is placed between the ceiling and floor for connection to upper radiator. This must be set as shown in plan, Fig. 6, using three nipples and three elbows to make the connection to receive the pipe that is screwed to the radiator valve. Always use this connection where the branch pipe from the riser is under the floor, as it allows for contraction and expansion. Be sure and have the connection from riser to radiator drip back into the riser, and be sure that no water can remain in the piping, for if there is water in this connection there will always be a sound of boiling water in the radiator.

The lower radiator, Fig. 5, shows a connection with drip pipe from bottom of radiator connection. This connection can be used to connect a radiator that is any distance from the main steam pipe; the supply pipe to radiator to drip in the direction that the steam flows and the return to drip back to the return main. If the connection from the main steam pipe to the radiator is short, take the supply out of the top of the main and not from the side.

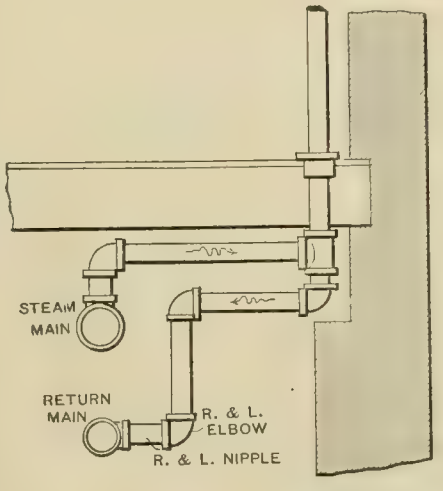

Fig. 1.—Showing One-Pipe Connection to Radiator.

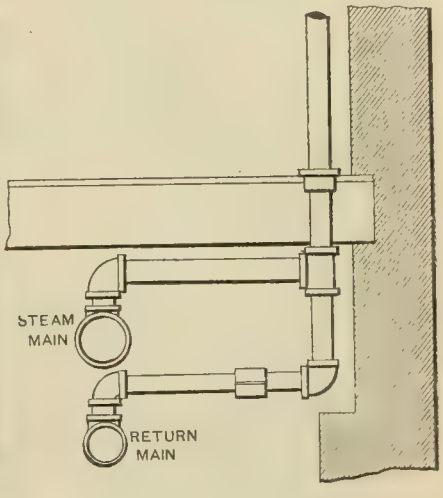

Fig. 2.—Showing One-Pipe Connection to Riser.

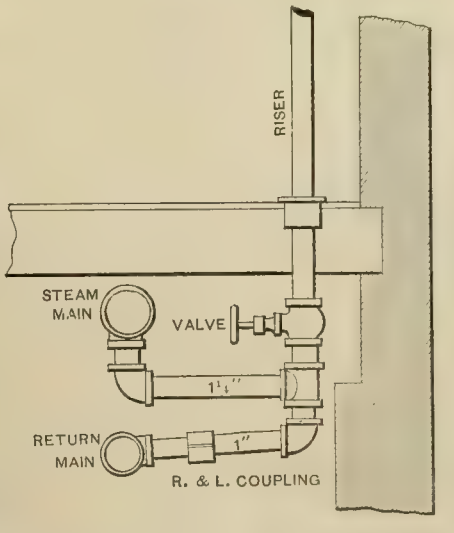

Fig. 3.—Branch Taken from Under Side of Steam Main with Valve in Riser.

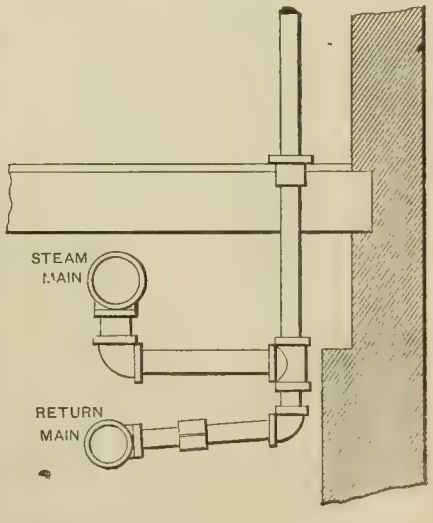

Fig. 4.—Branch Taken from Under Side of Steam Main without Valve in Riser.

ONE-PIPE STEAM CONNECTIONS.

Fig. 7 shows a side elevation of the main steam and return mains for connection to radiator and riser. Always connect all radiation on first floor direct to the main and not to a branch pipe that connects to a riser.

HEATING NOTES.

THE HARELL STEAM HEATING COMPANY of Dunkirk, N. Y., favor us with a circular calling attention to the Splendid Radiator, which is made plain and ornamental and connected with slip nipples. The company state that in the manufacture of these radiators nothing but the best materials are employed, and that the goods are guaranteed to be perfect in every respect. A table shows the list of sizes in which the radiators are made, together with the heating surfaces.

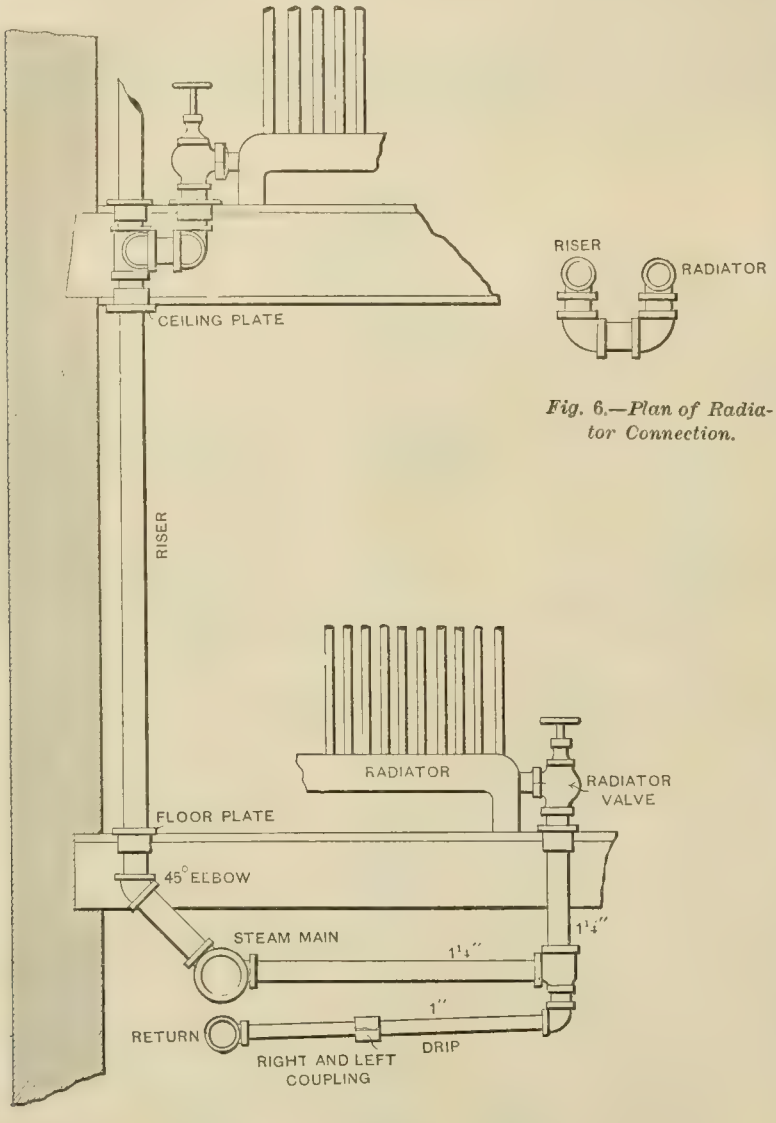

Fig. 6.—Plan of Radiator Connection.

Fig. 5.—One-Pipe Radiator Connections.

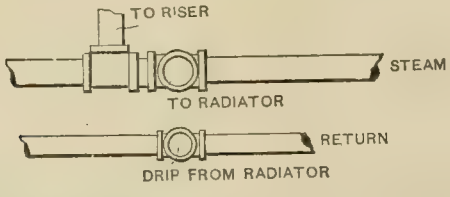

Fig. 7.—Side Elevation of Steam and Return Connections.

ONE-PIPE STEAM CONNECTIONS.

THE EXETER MACHINE WORKS of Exeter, N. H., and 32 Oliver street, Boston, Mass., have brought out an illustrated catalogue of Exeter safety sectional steam boilers for power and heating, and of Exeter steam and hot water radiators. The volume consists of nearly 50 pages of letterpress, printed in a tinted ink and profusely illustrated with engravings of the goods named. The frontispiece is a section through a private residence, showing the manner in which the Exeter steam heating plant is installed in connection with buidlings of that character. An interesting feature of the catalogue is a general view of the company's works and a plan view showing the relative position of the various buildings and departments. In their announcement to the trade they state that they commenced the manufacture of engines, boilers and steam-heating apparatus more than a century ago with a small plant and their sales territory confined to the New England States. Since then they have erected extensive additions to their works, employ a large force of men, and their product may now be found distributed throughout all parts of the United States and in many foreign countries. The Exeter boilers and radiators are carefully illustrated and described, and the catalogue, as a whole, is likely to prove valuable to those in the trade into whose hands a copy may come.

THE FRIENDS in the trade of F. A. Smith will, no doubt, be interested to learn that he has associated himself with the William H. Page Boiler Company of Norwich, Conn, taking entire charge of the sales department. We understand that all business will be conducted through F. H. Patrick, superintendent of the company, and Mr. Smith of the department named. Mr. Page has perfected the invention of a fine line of house-heating boilers, for both steam and hot water, and patents have been secured covering all points on these constructions, including the regulator by which the draft is controlled.

THE NEW YORK OFFICE of the American Boiler Company presents an attractive appearance to the steam and hot water buyer, as in it there is to be found a fine display of samples painted with gilt bands and gilded lettering. The Florida line is represented by a No. 120 steam boiler for soft coal, a No. 16 and No. 25 single boiler for hard coal, a No. 50 double boiler and a No. 58 heavy duty boiler. The Spence line is shown by a No. 10, 30, 45 and 60 boiler, and the Perfect line by a No. 22, 25, 27 and 30 boiler; a No. 12, 16 and 20 Little Giant; a No. 13 and 21 Tropic with magazine, and a No. 501 Modern, and a No. 250 Soleil complete the finished samples. Some partially erected boilers, as well as sections of boilers, and some grates, show the internal construction, operation and convenience of the goods. Heating literature is freely distributed, and the visitor is sure to add to his store of information.

THE H. B. SMITH COMPANY, Westfield, Mass., have taken two stores, 133 and 135 Centre street, adjoining the old stand at 137, and make a very handsome showroom. The walls are light blue, with dark cornices and decorations. At the front, by an ingenious arrangement of differently decorated radiators of various sizes and colors, is produced a very pretty effect. The display is made up of the Golds indirect pin radiator, the Reed radiator in single and double column; the Union radiator, with its central and two side columns; the Champion Union, the Royal Union and the Imperial Union, the latter being of ornamental design and handsomely decorated in two colors of bronze. Along the walls are arranged Nos. 4, 4½ and 5 Mills boiler, a No. 1 and 2 Mercer boiler and a No. 1 and 2 Golds Boiler, the No. 2 being shown in a wood casing, painted to represent brick, and with a stack of pin radiators showing a central plant for indirect heating. A Cottage boiler occupies a prominent place, and is intended for heating small buildings. As the new showrooms are on the corner of White street, the wall is used for a conspicuous sign, enumerating the different goods, while gilt letters on a black ground show "Steam and Hot-Water Heating" on a large sign on the Centre street front. A comfortable reception room occupies a generou space, and is doubtless the scene o many business transactions. The engineering and drafting department wil remain at 137, and have more space.

JENKINS BROTHERS of 71 John street, New York, have recently made some important improvements in their pressure valves, which cannot fail to interest the trade at large. One is in the nature of a new way of retaining the disk holder in place, the number of bolts in the valve bonnets having been increased as well as the thickness of the flanges. We understand it is the intention to make but one grade of valve, so that it will be unnecessary for customers to specially mention "valves for high steam pressure," as the goods placed on the market will be suitable for any pressures. Jenkins Brothers have also made an improvement in the manufacture of a rubber compound for use on high pressure steam. For nearly two years they have been using and testing this rubber compound in the manufacture of Jenkins' disks, and the results are said to have been more than satisfactory. The makers state that it is past the experimental stage and is considered by them the greatest advancement they have made in the manufacture of their specialties. In this connection it may be interesting to state that the improvements made in the manufacture of Jenkins Brothers' goods have not increased their selling price.

WE HAVE RECEIVED with the compliments of the author a pamphlet entitled "The Heating and Ventilation of Residences," by James R. Willett. The matter consists of an address delivered before the Engineering Societies of the University of Illinois, on March 23 of the present year, and covers in an interesting manner the topics mentioned. A large number of folded plates are bound in with the text, showing plans of houses and indicating the position of registers, radiators, pipe, &c. The pamphlet is arranged in such a way as will likely prove interesting to those having to do with heating and ventilation.

W. M. MACKAY, who has a large acquaintance in the steam and hot water heating trade, has recently severed his connection with the New York office of the American Boiler Company.

THE STANDARD HOT WATER HEATING COMPANY of Cleveland, Ohio, under the management of Richard Howse, run the Spence and Humber boilers for specialties and have installed a great number of them in that city and locality. Mr. Howse has had a large experience in Canada and is thoroughly conversant with the pressure system, with which he has had universal success, though the open tank system is used, as a rule, in his work here.

ONE of the large contracts now being figured on in Chicago is for the heating and ventilating of the Stock Exchange Building, La Salle and Washington streets. About 38,000 square feet of radiation will be required, and the cost of plant is estimated at $100,000.

THE ELECTRIC BOILER COMPANY of Rochester, N. Y., send us an eight-page circular of the Electric boiler, which they manufacture for steam and hot water heating and also for steam power. The merits of the construction are clearly set forth, while sectional views indicate the course of the products of combustion and also the circulation of the water. The manufacturers are also distributing to their friends in the trade a postal card on the back of which is the following inscription: "Wait for a shock from the Electric Boiler for steam and hot water heating."

SCRAP.

"HAMILTON'S BEST" redipped American roofing tin no longer needs a lengthy description of its merits to the buyer, as a wide introduction of it is now bringing in satisfactory orders to the house of John Hamilton, Pittsburgh, Pa.

THE CINCINNATI TIN PLATE COMPANY of Cincinnati, Ohio, have been granted a charter, with a capital stock of $10,000, for the purpose of engaging in the manufacture and jobbing of metals of various kinds. Howard Douglass of Cincinnati is prominently identified with the new company.

WITH A DISPOSITION to accommodate their customers McClure & Co., Pittsburg, Pa., find a ready market for their line of tinners' supplies among the trade, who are glad to get what they want so near home. The firm handle Tuttle & Bailey's registers, Peck, Stow & Wilcox Company's machines and tools, and a line of domestic and foreign tin plates, among which are McClure's redipped, McClure's hand coated, Taylor's old style and Hamilton's best.

HAVING now finished all contemplated extensions to their plant, the United States Iron and Tin Plate Mfg. Company, Demmler, Pa., have a large capacity and excellent facilities for turning out high grade black sheets for tinning. Their tinning department is well prepared in every way to turn out either bright or terne sheets with a coating on which they are willing that the trade shall pass judgment.

THE PHILLIPS TIN PLATE COMPANY, 200 Walnut place, Philadelphia, Pa., have started their new works, and state that they are now in a position to furnish promptly both tin and terne plates, heavy or medium coated. In addition to their former grades the company announce that they will make a "heavy dipped terne of the M F grade with metal more uniformly distributed and smoother finish than on the ordinary heavy plate; also a Pontymister grade terne and a good coke tin," in addition to their heavier grades.

HUGHES & PATTERSON of Philadelphia are just getting ready to start the second of the series of fine rolling mills they are putting up on the old Stephen Robbins mill site recently purchased by them. All the old buildings on this property have been removed and in their place have been erected the most substantial iron and brick buildings. In these new buildings is now being installed a fine rolling-mill plant. These mills are being equipped with the newest and most modern machinery, and labor-saving devices are used everywhere. The product in all the mills is handled by Ridgway steam hydraulic cranes in connection with a system of overhead runways. The roll trains are so arranged that they can be changed quickly by the Ridgway cranes. The cranes for this purpose instead of being placed on the floor level, as is the usual practice, are carried between the tops of adjacent housings, thus being up and entirely out of the way. A large tinning plant is also being added to the works, the machinery for which to a large extent has been imported from Wales.

A bore hole at Paruschowitz, Silesia, Germany, had marked a depth in May of 2000 meters, or 6562 feet. Boring will be continued as far as possible. The deepest bore hole hitherto is that at Schladebach, Saxony, which is 1748 meters, or 5735 feet.

Treasury Decisions.

Drawback on Terne Plates.

TREASURY DEPARTMENT, MAY 11, 1893.

SIR: On the exportation of terne plates in sizes 14 x 20 and 20 x 28 inches, manufactured by Merchant & Co. of Philadelphia, Pa., from imported pickled or smoothed or cold rolled black plates, a drawback will be allowed equal in amount to the duty paid on the imported black plates used in the manufacture, less the legal deduction of 1 per cent.

The drawback entry must specify the number, brand, size, gauge and net weight of the finished terne plates in each package to be exported, and the number, size, gauge and net weight of the imported black plates used in the manufacture of such terne plates.

The manufacturers shall be required to state in their declaration on the entry that the terne plates were manufactured and packed in the manner described in their sworn statement dated April 26, 1893, and to furnish the proofs of identity prescribed by article 758 of the Customs Regulations of 1892.

The statements in the entry as to the quantity, sizes and weights of the terne plates to be exported shall be verified by an examination of the packages and their contents and by such test weights as may be necessary, and the quantity of the imported black plates used shall be determined on the liquidation of the drawback entry by the weigher's return made at the time of the importation.

Respectfully yours,
C. S. HAMLIN, Assistant Secretary.
COLLECTOR OF CUSTOMS,
Philadelphia, Pa.

George F. Brandan of Cohoes, N. Y., has invented a car brake which may be used either on steam or electric roads. The brake consists of a shoe with a frame made of iron which comes into contact with both the car wheel and the rail at the same time. A cable aids in the adjustment of the brakes, which is operated by the motorneer. A test of the new invention has been made on the Troy, N. Y., city railroad.

What seems to be showing for a new gas district has just been tapped south of Homestead, Pittsburgh district. Some time ago Munhall & Scott drilled a well on the S. A. Morrison farm, which was a good gaser, and last week they drilled in another, which has an estimated pressure of 150 pounds to the minute through a 6-inch casing. It is making gas from the Gordon sand. This well is about 5½ miles south of Homestead.

Four 13-inch guns needed for the new battle ships have been finished at the Washington Navy Yard. Each of these ships will carry four of these guns, mounted in pairs, in turrets forward and aft.

Fifteen hundred poles and 450 miles of overhead wire are to be removed during the current year in New York by the Metropolitan Telephone & Telegraph Company.

The Pottstown Iron Company of Pottstown have sold 4800 tons of basic slag to Germany.

PLUMBING and GAS FITTING.

Howell's Flexible Water-Closet Supply Connection.

Geo. B. Howell of Philadelphia has invented and patented a flexible water-closet supply connection, which, it is claimed, secures to earthen water closets two important features—a flexible connection to the flush pipe and an absolutely air and water tight joint. The advantage of a flexible connection is appreciated as obviating the liability to breakage of the supply socket when subjected to undue strain during connection, sudden jarring, settling of buildings and other causes. The device is shown complete in Fig. 1, and consists of an interior annular collar, D, to suit the earthen projection or socket of the closet A, a brass spud, B, to which is attached an ordinary metallic screw coupling, and a molded rubber gasket, C, which, when placed within the socket A and expanded tightly over the collar D and against the interior walls of the socket by the introduction of the spud B, securely locks the spud in position and forms an absolutely tight, though flexible, joint. The spud is held in position by the projection E, and is prevented from turning during connection or disconnection of the coupling by two projections on the flange F, which fit into corresponding notches in the face of the earthen socket A.

Fig. 2 shows the rubber gasket placed in the socket ready to receive the metal spud. The shape which the gasket assumes when expanded by the spud is also accurately illustrated. The joint thus made has, we are told, been found to be not only flexible, but more secure than the joints made with sulphur and other hard cements, and to form a rigid connection to the earthenware. Mr. Howell has also adapted his device to fill the demand for a reliable floor connection. Fig. 3 shows the floor connection as consisting of a brass floor plate or flange, A, provided with an interior annular collar, D, and a beveled lower portion, E, adapted for soldering to the lead soil pipe, an ordinary conical water closet outlet, B, and a molded rubber gasket, C, which, when expanded tightly over the collar D, within the flange A, by the introduction of the conical outlet B, forms an absolutely tight joint, capable of resisting heavy pressure. The floor plate A and the rubber gasket C are shown in position ready to receive the closet outlet B.

Fig. 4 shows the parts securely bolted together and illustrates the expansion which takes place in the rubber gasket, and demonstrates the security of the joints. It is claimed that in addition to the security afforded by the use of this connection it is economical to the plumber, inasmuch as it entails very little labor to make a joint and renders leakage impossible.

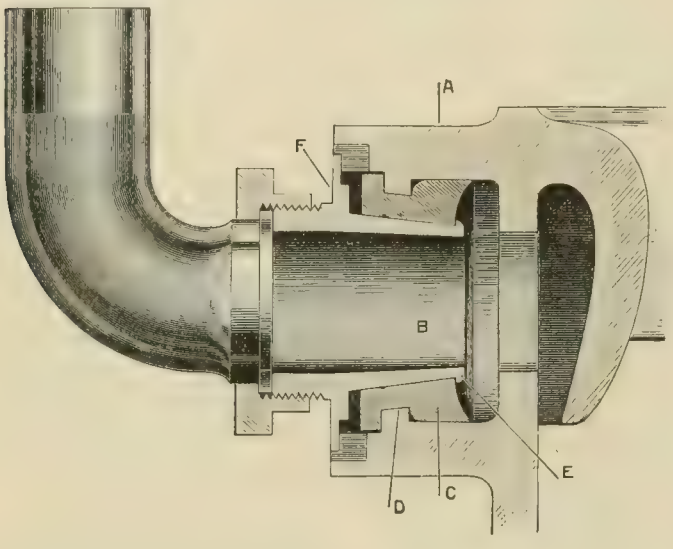

Fig. 1.—Sectional View of Connection.

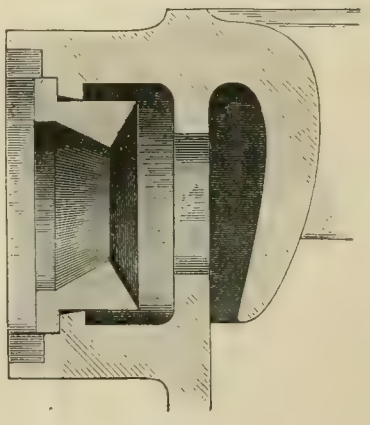

Fig. 2.—Gasket Expanded in Socket.

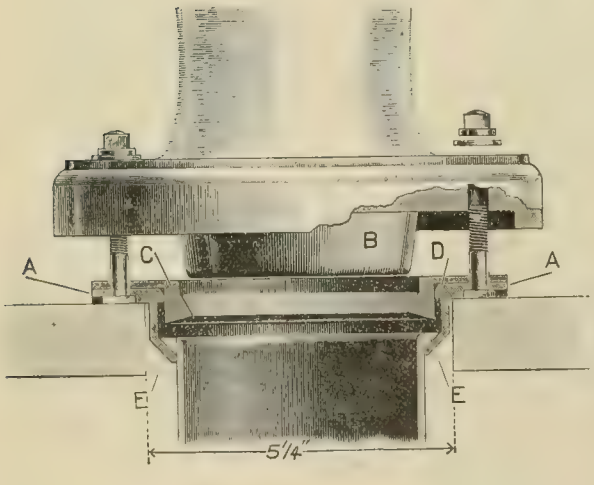

Fig. 3.—Floor Connection.

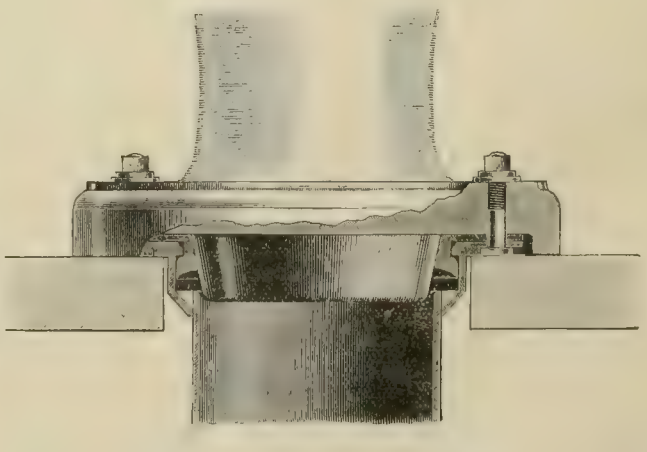

Fig. 4.—Floor Connection Bolted, Showing Expansion of Gasket.

HOWELL'S FLEXIBLE WATER CLOSET SUPPLY CONNECTION.

It will be noticed that the outlet of the closet projects into the lead soil pipe, and thus prevents any injurious matter from coming in contact with the rubber or solder joints. In making a joint the lead pipe should be cut so that its top edge will not project above the beveled portion E of the floor plate and the solder joint made as shown in the illustrations. Ample space is, however, afforded between the top of bevel, E, and the bottom of gasket, C, to allow for any reasonable irregularity in the end of the lead pipe or in the soldering.

Both connections have been placed on the market by McCambridge & Co., Limited, of Philadelphia, who, in a circular just issued, announce that a standard size outlet has been adopted for all earthen closets manufactured for them, in order that one standard size floor plate may suit closets of every pattern. They also announce their willingness to furnish brass gauges at small cost to manufacturers or jobbers desiring to adopt these connections. These gauges are for the use of the potters, who can make one size outlet as readily as another without any expense other than the cost of the gauge. Where for special reasons the outlet of a closet cannot conform to the standard gauge the firm can supply special plates and gaskets.

The Craft of Plumbing

Dr. William Garnett, principal of the Durham College of Science, in an address delivered recently at Newcastle-on-Tyne, England, before the North of England District Council of the Plumbers' Association, offered some practical remarks of great interest in relation to the training of plumbers. We reproduce here, for the benefit of our readers interested in this subject, extracts from Dr. Garnett's address which contain some valuable suggestions as well as information in regard to the methods of instruction practiced or proposed for adoption in trade educational classes in Great Britain.

In defining the duties of the plumbing craft, the speaker said: "Etymologically, the plumber is a worker in lead. According to the modern meaning of the term, the plumber is one who supplies our houses and other buildings with pure air and pure water. As the chief contaminations, both of air and water, are those which arise from the waste of animal (and to some extent of vegetable) life, it is essential that the plumber should provide for the removal of such refuse, or, at least, should so protect the air and water supply that contamination is impossible, and this necessitates the withdrawal from the neighborhood of our houses of all decomposing or decomposable material."

IMPORTANCE OF DRAWING.

Dr. Garnett laid special stress on the importance, to the plumber, of a knowledge of drawing, saying: It will be generally admitted that the essential feature of a craftsman is that he should be a master of his handicraft. In every large piece of work the pencil, or some substitute for it, must precede the ordinary tools of the workman. Drawing is the first stage of the work, and if the operative is to gain a leading position in his craft he must be able to make his own working drawings; but whatever position he attains, if he is to undertake any responsibility at all, he must be able to read a drawing, and the best way to acquire this art is to learn to make drawings himself. A working drawing is not a picture of the work to be carried out. A photograph of the actual thing would often be of comparatively little assistance to the workman who has to make it. A working drawing is a conventional representation of a solid piece of work by means of plane drawings, each of which represents, in accordance with certain geometrical laws, one aspect of the solid, while in many cases a pure symbolism is used which has almost as little connection with the true form of the solid as has its name when printed in ordinary Roman type. To combine together in the mind plan, elevation and sections, with all their dimensions as marked or represented to scale, and to picture in the imagination the thing represented, is to read the drawing, and this is as much an art as to mentally picture a landscape, or the heroine of a novel, from a letterpress description.

SYSTEM OF DRAWING INSTRUCTION.

Let us then, said Dr. Garnett, commence the out-of-shop training of the apprentice by teaching him to use his pencil, first by making freehand sketches of all the tools in his kit; then of various forms of traps and other appliances which he meets with in his every-day work. He will soon find out for himself that freehand sketches of things—as they appear—are insufficient to reveal their hidden constitution, and will probably of himself make sketches of the internal economy of the apparatus which he attempts to describe; that is to say, he will attempt to draw in section. Then he must be shown how to select his points of view for external sketches and his planes of section for sectional drawings, so as to secure a complete description of the thing represented. Provided with a rule, he should be taught to measure his model and to mark the dimensions properly and systematically on his drawings. For many purposes such dimensioned sketches, if executed with reasonable care, would suffice, but for planning and taking out quantities accurate drawings to scale are frequently desirable, and for marking off work on the bench a certain amount of geometry is essential. It is unwise at the commencement of his training to attempt to cram an apprentice with Euclid or the ordinary problems of practical geometry. Let him first become conscious of his need of geometry in his every-day work and be interested in his freehand sketches, and then let his geometry gradually grow out of his freehand drawing. The apprentice will very soon appreciate the advantages afforded him by straightedges, squares, compasses and scales, and will take pleasure in the solution of a geometrical problem when he has tried in vain to discover it for himself, not because the problem was given him as a kind of conundrum by his teacher, but because it arose out of his own necessities.

Simple problems in mensuration (or workshop arithmetic) will also force themselves on the notice of the apprentice at an early stage, and here I may point out that an intelligent approximation to a numerical quantity is far more valuable than 15 significant figures all accurately obtained, but with a painful doubt as to the position of the decimal point. It is well to know that the volume of a sphere is represented by four-thirds πr^3, where π stands for 3.141592653589793.., but for many purposes it is more useful to know that the volume of the sphere can be found approximately by taking one-half of the cube whose edge is the diameter of the sphere, and adding 5 per cent. to that half; in other words, by taking twenty-one-fortieths of the volume of the cube.

The same general principles of utility and practical applicability should guide us in the teaching of mechanics. In this subject very little should be attempted without experimental illustration, and this, as far as possible, conducted by means of workshop appliances and not with the models of the scientific instrument maker. * * * *

PROPERTIES OF HEAT AND WATER.

Then we naturally pass on to other problems in connection with heat; the expansion of water on freezing, the forces which may be called into play by this expansion, amounting to a pressure of 75 atmospheres or 1125 pounds per square inch for each degree Fahrenheit through which the water is cooled below freezing point. The arrangement of water supply so as to prevent the bursting of pipes through frost, the heat absorbed by water in becoming steam and given out again when the steam is condensed, the heat required to warm a cubic foot of air through any range of temperature, and hence the amount of steam or hot water required to warm the air which forms the ventilation current in our rooms and assembly halls. Then we come to more difficult problems in mechanics, such as pressure and its relation to head of water, velocity due to head, the momentum and energy of a moving column of water, the water seal of a trap when the water is at rest, the conditions under which water seals may be broken in consequence of the energy of the moving water, the waving out of traps, and the necessity for after flush, the pressure of the air, the principle of the barometer and the syphon, the action of the different classes of pumps, the pumping of hot water and the effect of the vapor pressure on the suction, the high pressure in front of a moving column, and the low pressure or suction at the side and rear, illustrated by the injector, the ejector, and its modification in the Banner cowl, the importance of this action in the arrangement of traps, the syphoning out of traps and the methods of preventing it, the use of the air pipe, shocks due to inertia, the necessity for screw valves on a high-pressure service, the air vessel applied to the force pump or lift pump, and the action of the hydraulic ram. All these points require the mastery of only two or three simple principles, which must be put before the apprentice in the most homely language, and illustrated by means of the most familiar examples and simple experiments.

The resistance of pipes to the flow of water and air and simple calculations of the flow through a given system of pipes under a given head or pressure should form one of the subjects for the most advanced class when preparing for the masters' certificate.

CHEMISTRY AND PHYSIOLOGY.

A little chemistry may well be introduced at an early stage; the experiments used to illustrate the teaching are sure to attract the students, and few subjects are of more importance to the plumber than an understanding of the most elementary principles of chemistry. Combustion and its products, the effects of combustion and respiration on the air, water and its chief impurities, soft and hard water and their action on the metals used by plumbers, the chemical properties of lead, iron, copper, tin and zinc, the action of dry and moist air and of the products of fermentation on these metals, solders and fluxes, and the methods of purifying solders; all these subjects may be taught without an undue amount of extraneous matter, and yet the teaching may be firmly based on fundamental principles. To the mind of every practical plumber many other points will suggest themselves, all of which may advantageously be introduced into the teaching of the evening class, because it is impossible to treat them adequately in the commercial workshop.

But, in addition to knowing how to design and carry out his work, it is very desirable that the plumber should understand why all the precautions which he has to take are necessary, and be able to give a reason for everything he does. The object of his work is to maintain the human machine in health and comfort, and he ought, therefore, if only for his own sake as an intelligent being, to know something of the construction and mode of working of the machine itself. The elementary principles of physiology, especially with respect to respiration, the composition of pure and refined air, the analogies between an animal and a steam engine, and the points of difference, the quantity of air required to secure healthy conditions, the heat produced by com-

bustion within the animal body, the nature of ferments, and of zymotic diseases, the natural history of germ poisons and the influence of contaminated air and water on the spread of disease, are subjects which, if the plumber is to be a man, and not a machine, must be of vital interest to him. The same remark applies to the history of the materials which he uses in his every-day work. The ores of lead, copper, zinc, iron, tin, &c., and the methods of obtaining the metals and preparing them for the market, are subjects in which every apprentice should be interested, and which he may fairly claim to be taught in the technical class.

SYSTEM OF CLASS TEACHING.

The chief point to aim at in the training of the plumber is, however, not the introduction into his memory of so much information, but the formation of those habits of thought which will lead him to look at a question from every possible point of view, and even consider what will happen under contingencies which may be very remote, though possible. This habit of mind is the highest aim of education, and the chief problem of the teacher is how best to produce it. For this purpose it is doubtful whether any other method is equal to a well-designed system of class teaching. A sketch of some arrangement which is faulty, but the faults of which are not at once obvious, is shown to the class and the members are asked to point out the defects. If they fail to discover them the teacher helps them by "leading questions," taking care only to guide their thoughts to the discovery and not to reveal the answer. In this way the apprentices are led to think of what will take place under every condition to which the proposed arrangement may be exposed, and a habit of looking at a problem from all sides gradually grows in the pupils' minds. Erroneous views expressed by members of the class only afford opportunity to the teacher to guard his students against such errors, and frequently open up new fields of discussion. To make such a class successful the teacher must be equal to any occasion that may arise, and if questions are asked which he is unable to answer he must honestly say so. It is far better to postpone a question for consideration after further study than to give an answer which the students at once perceive to be shallow and evasive. There must also be the greatest confidence between the teacher and his class, and perfect freedom of speech, with only such discipline as is necessary to avoid waste of time.

PRACTICAL INSTRUCTION TO ACCOMPANY THEORETICAL.

In the majority of cases, it has been deemed desirable to associate with the lecture or class-room teaching a certain amount of practical work in a shop connected with the educational institution in which the class meets. In this workshop the teaching can be illustrated in a way which is impossible under the conditions which govern a commercial establishment, and special attention can be given to those operations in which the apprentice finds his greatest difficulties. For practical work, the class meets for, perhaps, only three or four hours a week during the winter, but the teaching thus provided may be made of very great value for the illustration of the ordinary class teaching and as supplementary to the regular workshop training. Isolated from these it is valueless, and may be pernicious. As a rule, it takes a young plumber four or five years of continuous work at something like 54 hours per week to become even moderately proficient in his craft, and even then he cannot rank as a first-rate operative. This being so, it is obviously absurd to suppose that the handicraft can be taught in a practical class which meets for only a few hours during the winter session. Possibly by such attendance a boy may be taught to wipe a joint; but to let loose upon the world a number of men who can pronounce that shibboleth of the plumber's craft, but are ignorant of the principles of sanitation, and of all the other branches of handicraft necessary to make a complete plumber, is a sin against society, and one fraught with the greatest possible danger to the public health.

Chicago Master Plumbers.

The first regular meeting in July of the Chicago Master Plumbers' Association was held at their rooms, 197 Madison street, Monday evening, July 10. The only business of importance transacted was the ratification of the resolutions adopted by the National Convention at Milwaukee.

New York Trades School.

The catalogue of the New York Trades School for the thirteenth season, which commences October 16, is just being distributed. The front cover shows a half tone engraving of the school building at First avenue, Sixty seventh and Sixty-eighth streets, New York, and gives a list of the trades in which instruction is given in the evening and the day classes, with the statement that the work done by the pupils of last season can be seen on week days and Sunday afternoons. Names can be entered for the different classes beginning October 2, on payment of the fees. A list of the trustees and trades school committees is followed by a short history of the school, the Auchmuty system, its intentions, methods and success. Half tone engravings are used in connection with the different trades to show the high character of the work of which the graduating classes are capable.

Evening classes will receive instruction Monday, Wednesday and Friday evenings from 7 to 9.30 o'clock, the age at which applicants are received being limited, varying from 16 to 18 up to 21 to 24 years, and the fee for the course ranges from $12 to $25. Evening instruction begins at stated dates, and is given in bricklaying, plastering, plumbing, carpentry, house painting, stone cutting, fresco painting and blacksmithing. Instruction will be given to day classes in plumbing, house and fresco painting, sign painting, printing, carpentry and bricklaying. The fee for the course varies from $25 to $40, and the hours from 8 a.m. to 4 p.m. and 2.30 p.m. on Saturday.

The plumbing class is under the supervision of the Trade School Committee of the Master Plumbers' Association of New York, who have appointed John Delehanty superintendent of the plumbing department. Manual instruction will be given in 16 different kinds of work and in miscellaneous work where sufficient proficiency has been made. Scientific instruction will be given on the proper arrangement of service and waste pipes and drainage and ventilation under eight separate heads, followed by miscellaneous instruction. At the end of a course, the committee will examine the class, to ascertain their manual skill and scientific knowledge, when, if entitled, certificates will be given. Each pupil is furnished with a set of tools; has a place allotted at a work bench, receives careful instruction from skilled mechanics, as to the manner in which work should be done, with reasons therefor, and who see that it is done neatly and in a workmanlike style. Great care is bestowed on the scientific course of instruction, a printed form, giving questions with space for answers, being furnished each pupil. After the instructor writes the correct answer on the blackboard, it is copied by the class and its full meaning discussed. Diagrams of improper work are given for correction and afterward these become, with the blanks, the property of the pupil.

The same careful course is pursued in each of the other trades. A tribute is paid to the master associations in different lines of trade for the assistance rendered the school. Four thousand one hundred and fifteen young men have attended the school from 38 different States and from Canada. A plan and view is given of the lodging house erected to accommodate pupils, which provides comfortable rooms reasonably, the only restriction being that all lodgers shall be in by 11.30 p.m. An interesting feature is a four-page sheet that accompanies the catalogue, which contains extracts from letters received from pupils of previous seasons relating their success in getting work at wages which highly commends the efficiency of the school.

TRAPS AND VENTS.

L. L. CAMP, New Haven, Conn., one of the directors of Peck Bros. & Co., is in Chicago visiting the World's Fair.

THE HENRY HUBER COMPANY, dealers in sanitary specialties at New York, Boston and Chicago, have issued a very handsome volume of 206 pages, illustrating and describing in a brief manner the line of plumbing goods manufactured by them. It is known as Catalogue C, and is substantially bound in stiff board covers. Water closets are shown in many different styles of hard wood cabinet finish; cisterns and seats, plain, embossed and decorated earthenware, lavatories, bathtubs, earthen laundry tubs, sinks, urinals, &c., are shown complete; also the separate fixtures only. Decorated wash basins are illustrated in colors. Particular attention is directed to Boyle's pneumatic closets.

THE STANDARD MFG. COMPANY, Pittsburgh, Pa., take considerable pride in having furnished enameled bathtubs, lavatories, water-closets and complete outfit for several bathrooms for a residence, whose owner had been looking up plumbing goods in a number of large cities. With some recent changes their capacity for turning out enameled baths runs up considerably above 100 every day.

AMONG the members of the Arion Society of Brooklyn recently visiting the World's Fair was Arnold Beher, manager of Peck Bros. & Co.'s New York branch.

The naval gun cotton factory, recently burned down at Newport, will probably be rebuilt. Gun cotton is the high explosive of our navy. It is used even in the shells of the "Vesuvius," although she continues to be called a dynamite cruiser. Hence it is desirable to keep up the arrangements for producing it to a high state of efficiency. Besides, excellent experimental work is done at Newport, so that in the great future of high explosives it is necessary that the Navy Department should have the best appliances at its command.

The Foundrymen's Association.

The regular monthly meeting of the Foundrymen's Association was held at the Manufacturers' Club in Philadelphia on Thursday, July 6, Thomas Devlin of Thos. Devlin & Co., Philadelphia, occupying the chair in the absence of the president. The attendance was not so large as at previous meetings.

The minutes of the last meeting were read and adopted.

The Executive Committee reported that at its last meeting some discussion took place in regard to the circular recently issued by the association to other associations formed and forming, and it was finally arranged to await answers from all points, no action in the meantime to be taken and no departure from the usual proceedings of the association to be made It was desirable, however, that the association should help other bodies in any way possible calculated to benefit the foundry trade all over the country. As to the state of trade, the report stated that almost every foundry had taken steps to reduce the cost of production, although the price of labor remained the same as for years and was an important factor in the case. It seemed as though something should be done to make both ends meet at the end of the year. At the low price of castings in the open market it would seem that the only remedy would be a reduction in the cost, or a higher price for the products. The committee invited discussion upon the report.

The Special Committee, which includes the Price Committee, then reported by sections. P. D. Wanner of the Mellert Foundry & Machine Company of Reading, Pa., representing the iron-pipe trade, reported that in that line the trade was holding its own very well under the present condition of affairs in the country. Pipe foundries, so far as he knew, were pretty well filled with orders, and were particularly pressed on some sizes of pipe. Prices remained about the same, although they may have run a little higher occasionally on sizes for which there was not a usual demand, but in general the prices were not as good as the demand would warrant. He supposed the condition was in keeping with everything else at the present time. Everybody seemed afraid to ask anything like a fair price or profit for their productions. A year of low prices would seem to be ruling very generally. In the East founders were a little timid on account of the Southern pipe makers. The condition of the market in the East might have warranted an advance in prices, but the life was knocked out of the trade by the low prices at which Southern founders were offering. Pipe was being delivered all through the East as far as Bangor, Maine, by Southern pipe founders, and in some points it had been offered at prices at which Eastern founders could not begin to produce. This competition, he said, of course tended to promote timidity, and sales were being made bearing the smallest possible profit in order to keep foundries going and men employed.

E. E. Brown, of E. E. Brown & Co. of Philadelphia, representing the sash weight section of the committee, in reporting for his section said that he was glad to say that a little improvement was noticeable, but there was still room for a large improvement, particularly in the New York market. In the Philadelphia and New England markets prices were fairly good, he might almost say profitable. In the New York market they were, if anything, lower than before.

Stanley G. Flagg, Jr., of Stanley G. Flagg & Co. of Philadelphia, representing the malleable iron castings section of the committee, had nothing to report. The trade was in bad shape and there had been no change of late.

R. A. Register, of Register & Sons, Baltimore, representing the cast iron soil pipe section of the committee, reported that the demand for stock continued good. He said that in view of the high quality of soil pipe required for the Philadelphia trade in order to comply with the sanitary regulations, an arrangement had been arrived at between the manufacturers for the purpose of elevating the standard of their respective manufactures. The arrangement come to will go into effect at once and necessitates an advance in prices.

The Riehlé Bros. Testing Machine Company were elected to membership in the association.

The secretary announced that Dr. Kirk, who had arranged to be present at the meeting and deliver an address on the subject of "Melting and Fluxing in Cupolas" had not appeared, and his absence was unexplained. There was present, however, Wm. C. Henderson, chemist for Thos. Devlin & Co., who would address the meeting on a subject of interest to all present. Mr. Henderson then addressed the meeting on the subject of

Chemistry as Applied to the Iron Foundry Industry.

He said: I have been requested to address you this evening upon the subject of "The Value of the Chemist's Services as Applied to the Iron Foundry Industry."

The methods employed by the chemist in arriving at conclusions are so imperfectly understood by the laity that the manufacturer of the crude products of iron is not always in a position to decide whether their adoption would be of advantage to him or not. I qualify the statement in this way, because in the higher branches of iron and steel making the chemist's position is of such recognized importance as to render impossible all thought of operating without him. I am persuaded that in the case of many foundrymen there exists a strong prejudice against any departure from their time-honored manner of running their foundries, which predisposes them to regard the work of the chemist as being an expensive theoretical nicety incapable of practical results of the character in which they deal. It would be well before passing judgment for each foundryman to ascertain just what the chemist can do, how he does it, and whether the same ends may be achieved in any other way. Investigation will show that in forming his deductions the chemist's mode of procedure is singularly simple, reasonable and practical. As a result of years of exhaustive scientific experiment, theory and actual practice, the records of which are most complete and voluminous, it is known that certain impurities in material produce certain characteristic effects upon the physical behavior of manufacture resulting from its employment, that certain combinations of impurities produce certain other effects, and that in the process of conversion, which is in every case a chemical one, these impurities may be eliminated, retained or forced into combination with others according to fixed laws and conditions to which they are subject.

I use the word impurities in its strict scientific significance, and it is not to be supposed that their presence is in every instance objectionable; for while the existence of some is attended with wholly injurious results, and the abnormal content of any is productive of pernicious consequences, it is at the same time due to the properly adjusted proportions of others that desirable requirements are met that would otherwise be impossible. To properly adjust these proportions to effect the physical constitution demanded in the final product calls for ability of the highest order; for the line, on either side of which an element may not enter into its composition without disaster, is not always clearly defined. The influence exerted by other elements present, in neutralizing or augmenting properties identical to one, and the modified reactions occasioned by a change of conditions—such, for instance, as conducting the operations in newly lined vessels—are mere hints as to difficulties presented; and it is in the solution of this problem that the chemist's capacity is unique; for equipped with this knowledge he proceeds to determine, with absolute accuracy, to what extent these impurities exist in the material at his disposal, and he causes at will their ultimate dispensation in accordance with the physical end toward which his efforts have been directed. This undertaking is, indeed, so formidable that one may well pardon, in those not familiar with the possibilities in the manufacture of the higher grades of iron and steel, skepticism as to its achievement. A glance, however, at the specifications to which the metal used in the construction of our nation's ordnance must conform will dispel any doubt in the matter, and this is but an instance of requirements the every-day fulfillment of which is made possible by the work of the chemist.

To the iron founder, perhaps, among the more direct and comprehensive advantages that would follow the employment of a chemist would be his ability in the purchase of material; to intelligently take advantage of low prices, and in only acquiring such as would be best adapted to his purpose; to tell whether or not he could make use of a material and what results would take place in the event of its use—and this, be it remembered, before the material in question is even purchased; to exactly reproduce physical qualities in manufacture, without using any of the original material, and in affording protection generally to the founder against deception; for, under the chemist's inspection, it does not suffice that certain material should have a good reputation simply, it following, of necessity, that such material must stand upon its intrinsic merit. Occasions are not wanting where imposition has been practiced in furnishing material of good quality until the reputation of the brand is fairly well established, when material of an inferior nature has been substituted.

Any attempt of this kind, where the material is subjected to chemical examination, would result in instant detection. I include under the general head of "material," pig iron, iron scrap, fuel, brick, clay, sand, oil and in fact everything used about a plant that is liable to any variation from a fixed standard or in which certain qualities are desired. In enumerating the many advantages

accruing to the iron founder from the employment of a chemist, it is presupposed that the work is in the hands of one who is in every way qualified and experienced, and who embraces also a thorough knowledge of metallurgy; that an unstinted equipment of the necessary apparatus, &c., is furnished him; that every reasonable facility is afforded him to properly carry forward his work, and that due attention is given to physical as well as to chemical testing, for it is only in their joint application that the full value of the chemist's work is realized in its entirety.

A word touching the relative value to the iron foundryman of physical as compared with chemical testing may not be out of place here. It must be obvious to all that the actual service to which manufacture is put when occupying the position for which it was made, constitutes the most complete physical test that it is possible to conceive, and as the chemist's knowledge has, in the first place, been derived from, and his sole aim is, in the last place, to meet, this test, it might be said that he is wholly independent of any system of tests other than chemical ones, and it could be so said with truth so far as present knowledge is concerned. But as the limit to learning has not yet been reached it is as an aid in advancing his information into unknown fields that physical testing is most essential to him; though of course, it is of great importance in checking his work. But what of permanent avail is accomplished by the application of physical tests to material the chemical composition of which is unknown. The very utmost that can be hoped from such tests is to establish the fact that a definite lot of material in hand is either good or bad. But absolutely nothing has been gained toward the estimation of future lots, every parcel of which has to be heated in the same aimless way, whereas a fact once established by chemical research remains fixed for all time. When it is known that a certain percentage of an element in a material under certain conditions produces a certain physical effect, every time these conditions are reached in this material having the same percentage of the element this identical physical effect is obtained and no other.

Some may argue that, because in supplying at a profit manufacture to the satisfaction of their customers, there exists no need for a change in their business policy. This sort of reasoning, aside from its inconsistence with the progressive spirit of the times, by no means shows that their output is the best that could have been produced at the same cost. That their customers are satisfied may simply be the result of their ignorance as to higher possibilities in such manufacture, and enlightenment in this matter will, doubtless, bring with it a corresponding loss of custom. The various shifts practiced by the iron foundryman with a view to estimate the value to him of certain material appear grotesque in comparison with the methodical system employed by the chemist, and I believe that very little is attempted beyond the testing of pig iron. In this instance the custom seems to be to charge a new iron, and if the resultant castings look all right the iron is considered good and is put on the list of good irons; but should the entire work of the molder be destroyed and a lot of metal to be remelted be the outcome, then the iron is regarded as bad, and that brand is to be ever after avoided.

This very often causes gross injustice to be done to the pig iron producer, for if it proves anything at all it simply shows it with relation to that particular lot of iron used, it being quite possible for the iron from the same furnace to be at one time in every way suitable for a certain purpose and at another totally unfit for use in like manner. But I go so far as to say that whatever the outcome of this test it need not necessarily prove anything at all; for in event of a satisfactory result by this test from the use of a certain iron, it is possible that the iron in question might still be such as would be unsuited to the founder's peculiar purpose, but has, in the process of melting, neutralized the effect of another iron in the mixture equally as undesirable from an opposite cause, and the effect has been due to mere chance, and *vice versa*.

It must be within the experience of every foundryman that dire results have taken place, even though he was using material with which he thought himself perfectly familiar and for which he is perhaps unable to account even to this day. He should bear in mind that impurities in his fuel and other material besides pig iron play a most important part in his operations; and, although these have not entered into his caculations, such failures may be directly attributable to their abnormal existence. Many foundrymen are wont to lay great store by a name, and certain brands of iron are known to them as good irons or bad irons; indeed, in some cases a particular brand of iron is believed by them to be absolutely essential in the manufacture of their castings. Certain wily pig-iron men practice upon this delusion and obtain $1 or $2 more per ton for their iron than it could be advantageously replaced for by a vastly superior article.

The fallacious nature of the belief that because an iron of a certain name has at one time given good results the same good results will always follow its future use, will appear when it is known that the variation, in even the same cast of pig iron, is sometimes considerable. Pig irons are commonly spoken of among foundrymen according to some physical quality which they possess, such as "soft," "strong," "tough," &c. They do not know what causes these irons to possess these physical qualities, but, by their demand for them have forced the pig iron producer to learn the cause, and in his effort to meet this demand have rendered the presence of the chemist at the blast furnace of almost universal necessity. At the mines he is indispensable, because the ore is sold according to the percentage of iron or other metal contained, and its freedom from deleterious impurities has considerable bearing upon its value. That he is not in more general demand among iron foundrymen would seem to speak well for the hitherto profits in the business, but as each year brings with it a demand for lower prices it is only a question of time when the manufacturers in this important industry cannot afford to make needless mistakes, and the chemist's identity with the iron foundry will be assured.

In each progressive step advanced in the development of iron, from its first imperfect reduction from its ores to the production of the nickel-steel armor plate which causes to crash into harmless fragments projectiles hurled with the most destructive force of which man is at present capable, chemistry has played a part second to none. In a word, every change that comes over iron in passing from one state into another is a chemical reaction, and to whom could its conduct be better intrusted than to the chemist?

At the conclusion of the address Mr. Henderson was tendered the thanks of the meeting.

Walter Wood of R. D. Wood & Co. of Philadelphia said it had always been a puzzle to him why chemists were not more useful to iron founders. Not that the iron founder was ignorant, but because of the elements or impurities to be found in pig iron. Founders remembered an iron that had plenty of phosphorus in it or a large amount of manganese or sulphur, and they avoided it. What they required was a No. 1 pig iron carrying a certain amount of carbon and silicon. In running a blast furnace the first three elements were elements which largely controlled the furnaceman's operations. The questions of carbon and silicon, elements which a foundryman mostly depended on, were conditions which a blast-furnaceman could not closely guarantee. Besides the assurance that there was no sulphur or other product deleterious to manufacture in the iron, it should be shown exactly what was the silicon and carbon in it in order to enable the foundryman to handle the metal carefully and understand it. To employ a chemist in a foundry without such assurance from the blast-furnaceman meant an analysis of almost every cast and every carload. Foundrymen were in the habit of judging as to the carbon by the color, and probably thus came to the conclusion that a chemist was not as useful as he might be, and trusted to the mixing of three or four different irons to strike an average, letting the mixer reduce that average to as near a certainty as possible. He would be glad to be corrected and have some light thrown on the question.

Mr. Henderson, in reply, said that a chemist could make any grade of iron desired, accidents excluded. The question of shrinkage was the main question a foundryman had to deal with. If the melting point of wrought iron was compared with the melting point of cast iron there would be found a marked difference in the number of degrees of heat necessary for the melting. It should first be ascertained what occasioned that tremendous difference, and a chemical analysis would reveal the fact that one was almost pure iron while the other contained what might be termed impurities. It was fair to suppose that the impurities were the cause of the change in the melting point. Certain impurities were found to be deleterious, such, for instance, as manganese, sulphur and others. In fact they would be objectionable unless handled with great care. Silicon had the effect of correcting shrinkage, for the reason that it had been ascertained that the purer the iron the greater the amount of heat required to melt it. It was a natural law that all bodies contract on cooling and expand on heating, consequently the greater the heat the greater the expansion. The farther apart the atoms of metal get when in a melted state the greater distance they had to come together in cooling. This was shrinkage. If the temperature of the metal could be reduced to the smallest possible degree and the metal held in fluidity, then would be reached the highest point from which shrinkage was to be ascertained, and in consequence the chemist selects an addition to the mixture considered to be the least deleterious to effect a reduction in the melting point of his metal. If he goes too far and uses too much silicon he

causes the article manufactured to be extremely brittle. Silicon has a tendency, when existing in high proportions, to make an article of low tensile strength, therefore it is necessary to know how far to go when using it.

P. D. Wanner thought that it was generally believed that the pig iron of the present day was not as good as it was 10 or 15 years ago. That was the opinion prevailing at Reading. Producers were careless as to the quality of ore melted and were forcing their furnaces with the object of turning out as large a quantity as possible without regard to quality, on account of the low prices current. This being the case, it became more important for the foundryman to mix his iron or to get to understand his iron so as to bring about good results. Silicon was very necessary in the iron used for making pipe, particularly in the larger sizes, so as to prevent undue shrinkage, and it could not be dispensed with. Iron possessing a good deal of that element was required. Too much caused the pipe to become brittle and thus entail a great deal of trouble, as he knew by experience. He had had trouble with a certain brand of iron which ran hard and white. He would like to know what was wanting in that case.

Several things, Mr. Henderson said, would cause iron to run white, sulphur having a remarkable effect. Sudden cooling would also cause the condition. It was likely, too, that the iron was low in graphitic carbon and high in combined carbon. Change in the temperature in melting when the iron contained a small amount of graphitic carbon would cause it to run white.

Mr. Wanner presumed that to meet the case it would be necessary to add another iron to the mixture sufficient to supply the deficiency existing.

Stanley G. Flagg, Jr., said that he had long intended to raise the question among members of the association as to whether it would be practical or possible for the association to go more fully into the technical part of the foundry business. He could not imagine a man melting a small heat of iron affording to employ a chemist. In Germany, foundrymen's associations such as this have technical connections. They sometimes employed a molder of large experience, and members requiring advice paid him for it at a rebate on fixed charges. In that way small consumers derived much benefit from the associations not otherwise available to them. If the membership in this association would combine and carry out a line of investigation it would prove very beneficial to all, and would result in information not open to individual members.

Mr. Wanner had no doubt the Executive Committee would be glad if the association would give the subject some thought. To have some one in the interests of the Foundrymen's Association to whom members with business large or small could turn for information was an idea worth following out. He supposed it would require something in addition to the ordinary fees of members to attain this end, but as one of the Executive Committee he should be glad to see what could be done.

After much discussion the matter was referred to the Executive Committee.

Mr. Wanner then stated that the Chamber of Commerce in New York, at a sitting that afternoon, had taken action in favor of the repeal of the Silver bill. A resolution, he said, was also passed that all boards of trade, industrial and commercial associations be asked or requested to take up the matter and express their views on the subject. He was of the opinion that the Foundrymen's Association had secured a very good foothold, and he saw no reason why its members should wait until they were asked to act in the matter, or why they could not, to some extent, take the lead in that direction. He thought they should help the matter along. Doubtless, all were rejoiced to know that Congress would meet in August, instead of September. It was obvious that they were passing through a crisis which had already hurt a good many of them, and the end had, possibly, not yet been reached. The general opinion prevailing appeared to be that the Sherman silver law was a bad law and had induced the present condition of financial affairs, and, therefore, the sooner it was repealed the better it would be for all. He submitted the following resolution:

Resolved, as the sense of this association, That we respectfully urge upon Congress, when assembled, the immediate and unconditional repeal of the silver-purchasing clause of the Sherman act.

After some discussion, the resolution was put to the meeting and carried unanimously.

A motion was then made that the resolution be sent to the Speaker of the House under the seal of the association and the signature of its authorized officers.

The secretary, Howard Evans, announced that the Western Foundrymen's Association held their first meeting in Chicago on May 25 last. The association was permanently formed and was following very closely the proceedings of this association. In regard to the circular sent to them inviting discussions and comparisons on subjects of interest to foundrymen in general, he was advised that the new association would be carried on separately and on its own basis, but would feel itself in touch with this association and be perfectly willing to send information on any subject which it was in their power to give. He had written their secretary stating that this association was national in character and both willing and anxious to help any association in the United States, with the idea of furthering the interests of the foundry trades. If after a time all the associations were found to proceed satisfactorily it might be found desirable to have a meeting on a large scale.

The meeting then adjourned.

What is claimed to be the largest girder ever shipped in one piece has been put in place in the new Broad street station of the Pennsylvania road at Philadelphia. It is 58 feet 1 inch long, 10½ feet in hight, and rests on a plate 2 feet 6 inches broad. The Philadelphia Bridge Company, its makers, claim that this giant, weighing 110,780 pounds, is the heaviest and largest steel girder ever turned out complete by an iron works in the United States. The girder is placed across Fifteenth street, on the south side of the station, and is designed to support the weight of the seven stories of brick of the office building on the Market street front.

The advisability of using sand filters in the Croton watershed, from whence New York receives its water, is now being considered. Although filter beds are used in England, there are none in this country built on a large scale.

FLASHINGS.

According to newspaper reports, a Tinners and Cornice Makers' Union was organized at Greenfield, Ill., on the evening of June 30, this being, we understand, the seventeenth union of this craft organized in the State. The officers are: Nicholas Smith, president; Peter Gillick, vice president; Herman Tittman, recording secretary; Frank Kibele, financial secretary; Frank Keys, treasurer.

A series of photographs from W. H. Mullins, Salem, Ohio, show some sheet-copper statues of Comedy, Music, Painting, Poetry and Sculpture for the Teatro Juarez, Guanajuato, Mexico. The statues are ten feet and the photographs convey the impression of superb workmanship and beauty, and they will doubtless prove very imposing ornaments to the building. High art in metal work is proved possible by the productions of this plant, and the satisfaction expressed by the patrons is incentive to continued effort in that direction.

Among the late contracts taken by J. C. McFarland, 2511 to 2519 State street, Chicago, can be mentioned the slate roofing, of which about 2500 squares will be required; gutters and conductors for the 25 buildings erected by the Whitman & Barns Mfg. Company at West Pullman, Ill.; copper, galvanized iron and tin work for the Market Hall at Pullman, Ill.; copper work and slate roofing for Medina Temple, Jackson street and Fifth avenue, Chicago; copper work and 225 squares of slate roofing for the Court House at La Porte, Ind.

S. D. Hicks & Son of 65 Merrimac street will remove about September 1 to 9 to 17 Bowker street, Boston, Mass., where they will have greatly increased facilities.

Neponset water-proof paper, the Cushman metallic shingle, Kanneberg's slip-joint eave trough and Kanneberg's patent folded lock seam steel roofing, with a variety of designs for siding and ceiling in iron and steel, make their way to the trade over a wide section from Canton, Ohio, where the Kanneberg Roofing Company have a well-equipped manufacturing plant.

J. H. Eller & Co., Canton, Ohio, have a fine plant right on the railroad, and an order for steel roofing, siding, ceiling or any of their specialties is apt to make a part of the next out-going freight.

The Columbia Roofing Company, Canton, Ohio, are acquainting the trade with the construction of their new and patented Columbia steel roofing by mailing a small section of the standing seam with their catalogue, which explains not only this specialty but their general line of siding, and eave-trough and conductors.

Much study is now being devoted to the question of oil for fuel for ocean steamships. The "James Brand," during a recent voyage across the Atlantic, used petroleum for three days and found it satisfactory in every water. The oil was fed to the furnace by means of jets of steam. The "James Brand" is of 3780 tons register, 345 feet long, 43½ feet beam, 29 feet deep, and is furnished with triple-expansion engines. The experiment will be continued, and if found to be of advantage petroleum will be used exclusively.

THE TIN SHOP.

Pattern for Two-Piece Elbow.

From B. E., *Baltimore.*—In the accompanying diagram is shown my "shop" method for obtaining the pattern of a two-piece elbow. In the diagram let A B C D represent the piece of iron intended for elbow. The allowance for joining is indicated by the lines E F and H G. Then E H represents the circumference of elbow. Let J K L represent the half profile, which is struck from the center M. Divide J K L into any convenient number of equal parts, as shown by the small figures. Divide the circumference E H into twice the number of parts as was the half profile J K L, and from the points thus obtained draw the usual measuring lines. From the points in J K L draw lines parallel with A D, cutting measuring lines of similar number, as indicated by the dotted lines drawn from points in J K L to lines of similar number in J N. These lines can be continued to similar lines in N O. By tracing a line through the points thus obtained, as indicated by J N O, the desired pattern is secured.

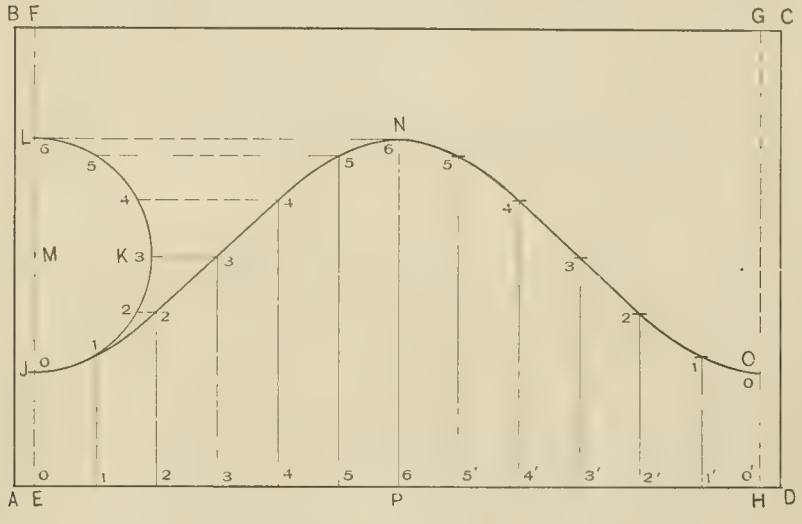

Fig. 1.—Method Suggested by "B. E." of Baltimore.

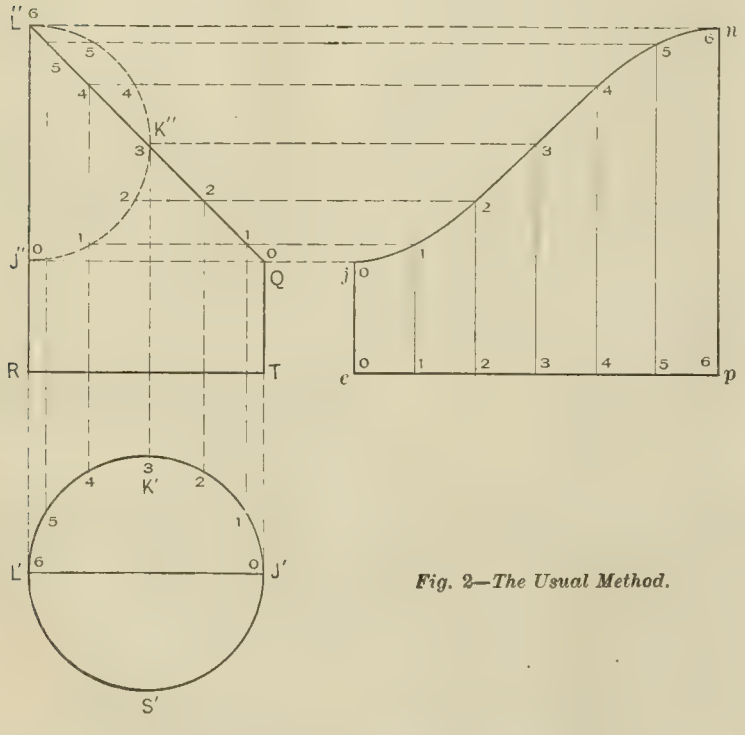

Fig. 2—The Usual Method.

PATTERN FOR TWO-PIECE ELBOW.

The usual method for obtaining the pattern is shown in Fig. 2. In this figure let L' K' J' S' represent the profile and R L'' Q T the elevation of one part of elbow, the diagonal line L'' Q representing the joint. To obtain the pattern, divide the profile into any convenient number of parts, and from the points thus obtained carry lines parallel with R L'' cutting the miter line L'' Q. On R T extended, as *e p*, lay off a stretchout line of whole or half of profile, divided into the same number of parts as the profile. In the present instance the half pattern only is shown, consequently *e p* represents the stretchout of L' K' J'. Through the divisions in *e p* draw the usual measuring lines. Carry lines from the points in miter line L'' Q, parallel with stretchout line *e p*, cutting corresponding measuring lines. A line traced through these points, as indicated by *j n*, will complete the half pattern. The other half can be obtained in a similar manner or by duplication. In this example we carry lines from L' K' J' of profile to the miter line L'' Q, and then from miter line L'' Q to the measuring lines. The same result is obtained by drawing lines from the divisions in the half profile J'' K'' L'' to the measuring lines, as has been done in Fig. 1.

A Test of Carpenter Shells.

A highly successful test of the largest armor piercing shells was held at the naval proving grounds, Indian Head, on the 5th inst. The shells were the product of the Carpenter Steel Company, and represented a lot of about 250 which the Government has contracted to purchase from that concern. The tests were under the personal supervision of Commodore Sampson, chief of the Bureau of Ordnance. Each shell weighed 850 pounds, and is intended for operations against armor. Such shells do not contain bursting charges, but cause damage by the force of impact alone. The shells were discharged against one of the several Creusot plates recently bought by the Navy Department for experimental purposes.

Only two shells were tested. The first had a velocity of 1300 feet a second. It penetrated 16 inches of plate and backing, rebounded and was found to be only slightly distorted in body. The second shell had a velocity of 1325 feet a second. It went through both plate and backing and fell 9 feet in rear of the target. It was practically undeformed when examined. In the contract requirement shells of this large caliber must, to be acceptable, go through plates without serious distortion or break. Both shells used met the requirements in a satisfactory manner, and the lot which they represent will be accepted.

Official returns for the middle of June published by the German Government show that the outlook, which was not very bright before then, has become very serious, particularly with regard to the hay crop. Some newspapers urge the suspension of import duties on fodder to follow the precedent established by France.

THE LETTER BOX.

What Is the Best Roofing Tin?

From B. S. K., *Syracuse, N. Y.*—I would like to have your opinion on the following. I have a specification reading thus: "Roof to be covered with 14 x 20 I C best roofing tin." Now I estimated on a Dean grade, worth about $6 a box, but the owner tells me I must put on a particular brand of the heavy coated guaranteed plate, that being considered the best in this city. I expect to fulfill the specifications and am at a loss to know what to use. One says Dean grade is considered the best, and cannot be construed to use what is known as an extra roofing plate like guaranteed plate. I also wish some of your readers would express their opinions in this matter.

Note.—The word "best" roofing tin can be read in two ways, as it may be considered of the usual run of plates, under which interpretation our correspondent is correct in taking Dean grade as fulfilling the specification. It is possible, however, in the local trade, the best plate may mean this particular brand of old-fashioned roofing plate to which he refers. In this case, local opinion would decide in favor of the special brand. When it comes, however, to claiming that one of the certain old-fashioned plates is the best, there would immediately be cause for endless dispute. There are several old-fashioned plates in the market, each of which is claimed to be the best, and to use one above the other when neither is specified by name would be making an invidious distinction. We think the most of our readers will agree that the highest grade of unguaranteed plate is probably what is meant in the specification. We would like, however, to have a general expression of opinion in this matter.

Trouble with Water Back

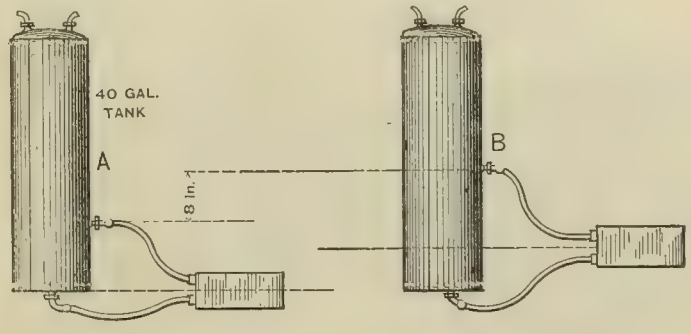
From J. P. & S., *Haddonfield, N. J.*—We would like to hear, through the columns of *The Metal Worker*, from some of the correspondents in regard to trouble we are having with a water-back used in a brick-set range at the back of the fire box. We have taken out the water back and thoroughly cleaned it; taken the upright boiler, which is located in the bathroom over the range, to the shop and examined it, and also put in a new copper tube. We have replaced everything in proper position, put in larger lead pipes, and yet, notwithstanding all this, the water back is so cold that you can lay your hands on it while there is a hot fire in the stove. The lady of the house told us that she does not get the water hot enough to wash dishes. Now, we would like to know if there can be anything in the iron of which the water back is made which keeps the heat from striking through it. The range draws all right, there being no trouble with the draft, and the stove bakes well; in fact, everything works satisfactorily except the water back.

Note.—If our correspondents had furnished a sketch, we might have discovered what the difficulty was with the heating apparatus. As a matter of fact, it is hard to believe that the iron can have anything to do with the heating of the water back. Iron always conducts heat, and if the arrangements are properly made and the water back of ordinary construction, we fail to understand why the heat does not go into the water. Nothing in the iron itself would interfere with its transmission. If any of our readers can offer suggestions, we would be glad to hear from them.

Heating Range Boilers.

From J. H. B., *Lincoln, Neb.*—Which one of the range boilers shown in the accompanying illustration will heat the water in the shorter time?

Note.—We have reproduced our correspondent's sketch in the illustration.



Heating Range Boilers.

The difference between the arrangement in plan A and plan B is that the water back is at a different hight and the return pipe is higher in the second case. We would like an expression of opinion from our readers on these two constructions, assuming that the water back is the same in both cases, and that all the connections are equally well made, by which we mean that there are easy bends and no obstruction in the pipes, and that the pipes are of the same size. In plan A, it will be noticed, the water back is below the bottom of the boiler, but the upper pipe is nearer the bottom than in the case of plan B. The fact that the water back is low would have a tendency to increase the circulation, but, on the other hand, the higher return pipe in B would tend to facilitate circulation. We would like to have the opinion of our expert readers as to whether the higher return or lower water back is of the greater advantage in promoting circulation.

Laying a Tin Roof.

From J. G. E., *Noblesville, Ind.*—In answer to the inquiry of "C. S. P.," in *The Metal Worker* of July 1, I advise him to lay his roof with all flat seams, one sheet at a time, and fasten the same well with cleats not more than 1 inch wide, for a wide cleat has often ruined an otherwise good roof. Where there is a fall I prefer a standing seam and I have no trouble here in Indiana with a fall of ¾ inch to the foot; 1½ inches is, however, better.

Trouble with Well Cooler.

From C. S. B., *Hanover, Pa.*—I notice in *The Metal Worker* of July 1 a sketch of a well cooler submitted by "P. R. F.," which has not given satisfaction. We have had trouble with several coolers in the same way and always found the difficulty came from a leak in the boiler or a leak in the pipes. The warm water coming through the pipes and leaking into the well, no matter how small the leak, will, in the course of a little time, make the well water the same temperature as the hydrant water. I think if your correspondent will take his boiler and pipes out and examine them closely he will find a leak somewhere. I simply offer this as a suggestion.

From H. W. W., *New York.*—In my judgment the difficutly met with by "P. R. F." of Virginia in his well cooler is due to its position. It should be stood on end with the sink drawing supply from the bottom and the feed entering at the top, with a return bend to prevent the water passing directly across the tank, which it, no doubt, does with the present arrangement, as the feed and discharge pipes are of the same size. When the faucet at the sink is opened the velocity of the water in the feed pipe is equal to that in the discharge, and, therefore, owing to the high speed of the water entering the tank, and the outlet being directly opposite, there is nothing to prevent it from passing through the tank in a direct and compact current. Its action is similar to that of the injector or water syphon. In any case, the supply should be at least 1 inch, with a return bend or scattering plate to check the direct currents.

Bathing and Washing Facilities in a Brooklyn Factory.

Increased attention is being paid to the proper heating, lighting, and ventilation of workshops and factories; employers recognizing that improved conditions in these matters, while ministering to the health and comfort of their work-people, tend also to their own advantage in inducing better work and more of it. This is all matter for congratulation, and very satisfactory so far as it goes. But there seems to be something yet to be learned in respect to the provision of better washing and other sanitary facilities, for, as a general rule, such provision falls far short of what it might be. Baths are rarely found in American factories, nor any facilities for washing out soiled clothes. Yet the advantages that might be gained, both by employers and employed, in the provision of such comforts are worth consideration. While improving the health and comfort of the men, the refreshment of bathing and enjoyment of clean clothes would undoubtedly give them a greater capacity and energy for their work; body and mind alike would be refreshed, and the refreshment would react upon their laboring qualities.

In Germany, as we understand, a system of baths and wash places has been adopted with much success in several factories, similar to that in use in the schools and public institutions of that country—namely, the shower or rain bath system. Results have, it is said, shown a marked improvement in the general health and working qualities of those using them. The special recommendations of this system are that it is more economical of space; and that men can get a thorough wash-down in a short time—from three to five minutes—with great economy in the amount of water used. It can also be introduced at a comparatively small cost; and, in large industrial establishments, would be found to be of great value to and appreciated by the workers, especially those in cities, where facilities for maintaining personal cleanliness at home or elsewhere are often very small.

This matter has, we understand, been in the minds of several employers of labor throughout the country, but various reasons have militated against its practical adoption. Among these employers is J. H. Williams, head of the firm of J. H. Williams & Co., the well-known makers of drop forgings of Brooklyn, N. Y. Mr. Williams, after long consideration and investigation, convinced himself of the material advantages which would result from supplying his men with bathing facilities, and accordingly decided to adopt the shower-bath plan as the best method for overcoming the objections as to cost, space, loss of time, &c., which in this connection were urged with reason against the bathtub system. Taking as his model the People's Baths of New York City, where the luxury of a shower bath, with towel and soap, is provided for the small sum of five cents, he built a similar bathhouse in connection with his works, which is the first on this principle yet introduced into any American factory.

Space for the new bathing room was found at one end of the lofty forge-shop in the works of the firm which are located at 9-15 Richards street, Brooklyn. A new story was "hung on" to the roof, forming a room, as shown in the accompanying plan, Fig. 1, 50 feet in length and with an average width of 19 feet. On one side of the new room are placed 12 shower baths, similar to that illustrated in Fig. 2, consisting of small cubicles with ample room for a man to stand and move in. In each is fixed a large overhead spray connected to pipes conveying hot and cold water. The hot water pipe is connected with the heating system in use all over the factory, and the cold with the street main. These can be regulated so as to obtain any temperature desired by the bather. A rack with soap is fixed on the wall; and the water is conveyed off by a trough at the

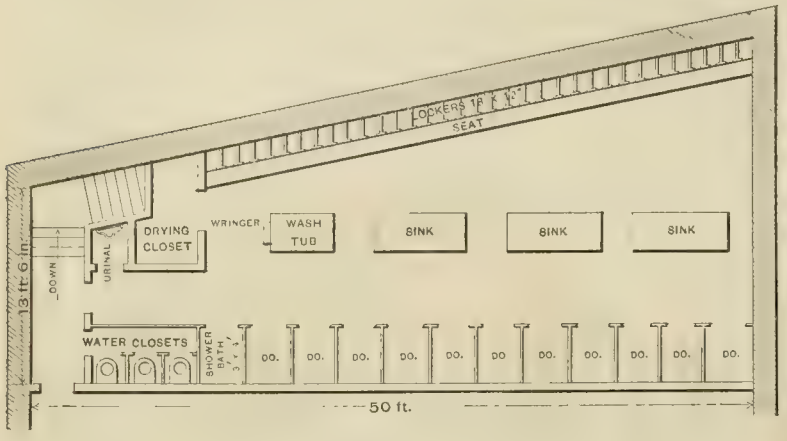


Fig. 1.—Plan View of Washhouse.

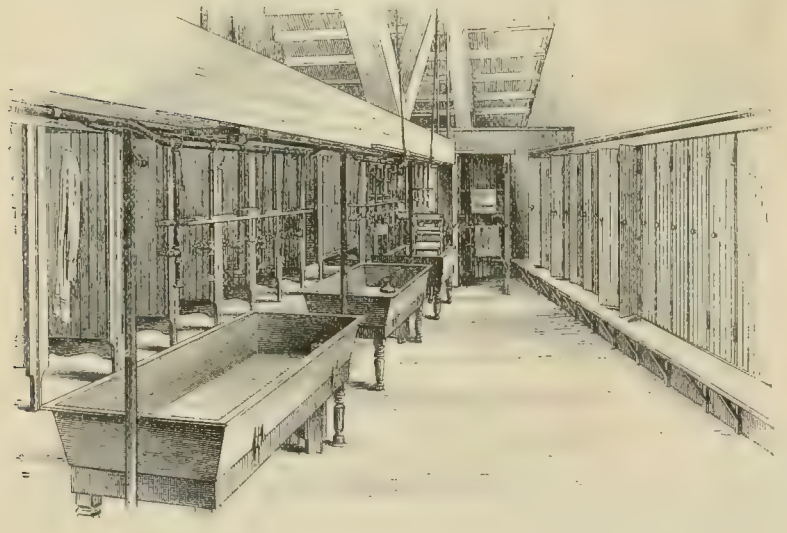

Fig. 3.—General View of Washroom.

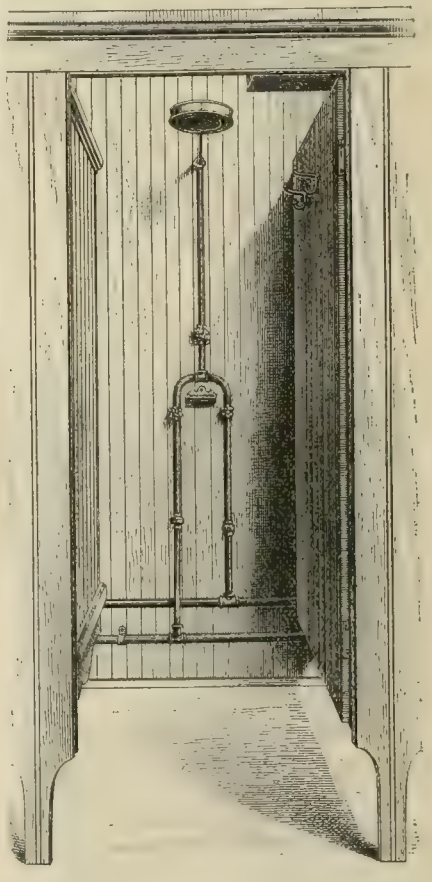

Fig. 2.—Shower Bath Compartment, Showing Piping.

BATHING AND WASHING FACILITIES IN J. H. WILLIAMS & CO.'S FACTORY, BROOKLYN.

side of the room, the asphalt floor having a double incline, which insures the ready flow of water. These bathing compartments occupy but a small floor space, being only 3 feet by 4 feet in dimensions.

It is calculated that the men will take but from three to five minutes in getting a wash-down, so that a number can bathe in rapid succession; a great feature where all wish to bathe at the same time, as would be the case in large factories. The baths would probably be most in request at the close of the day's work, when men do not care to waste their time in prolonged ablutions, and yet can afford sufficient time to get a thorough cleansing by a shower bath on this principle. The water each would use, too, would be but about one-seventh of the amount required for a tub. No attendant is necessary to fill tubs, &c., and no cleaning up is entailed afterward, as the water runs off immediately, the cleansing being automatic.

There are other advantages in the shower-bath system also, in that no soiled water touches the body, consequently the cleansing is more thorough and there is no danger, as in the bath-tub, of communicating disease. The baths are ready, too, at all seasons and times, and there is little apparatus to get out of order. It is believed that in hot weather the men will often utilize a portion of their dinner time in getting a "refresher" in the bathroom, and will go back invigorated thereby to their afternoon's work.

The system appears to be one that would recommend itself to employers solicitous for the comfort and health of their men. It is also calculated to educate the men in habits of cleanliness and order, and is altogether a step in the right direction.

In addition to the shower baths, the washroom is provided, as shown on plan and in the general view of the room, Fig. 3, with three large cast-iron troughs, in which those men can wash themselves who do not require a regular bath. These are each fitted with a row of half a dozen sprinklers, so that the men can get a *douche* for their heads. The troughs are filled with warm water just before the dinner and knocking-off hours, by an attendant, who is able to keep the whole place clean with but very little trouble.

There is also a further laudable innovation connected with this institution. A matter which has long troubled workingmen is the disposal of their working clothes. These become soaked with perspiration in a place like a forge shop, and when taken off at the day's end must be either carried home to be washed, or hung up in the shop to dry and put on next day in a sour, unpleasant state. Usually, the latter alternative is resorted to. In this washhouse a large soapstone sink is provided, where the men can in a few minutes rinse out their soiled garments and pass them through a wringer attached to the side of the trough. A drying closet is placed at the corner of the room, where, by means of hot-water pipes, the clothes are thoroughly dried; and they can thus be put on next morning clean and fresh—a great boon to men who work in the heat of a forge shop, and are constantly in a condition of sweat, which soaks the clothes in which they work.

Opposite the bathing compartments is a double line of lockers, 80 in all, in which the men can stow their clothes. These lockers are high enough for hanging garments, and are provided with hooks and a shelf for small articles. At the foot of the lockers runs a shelf on which the men can sit down. The view, Fig. 3, shows only one row of these lockers. Another is now being erected above them. The water-closet facilities attached to the bathroom are exceptionally good and would do credit to any well-appointed house, being of the latest type, with toilet paper and washing facilities provided.

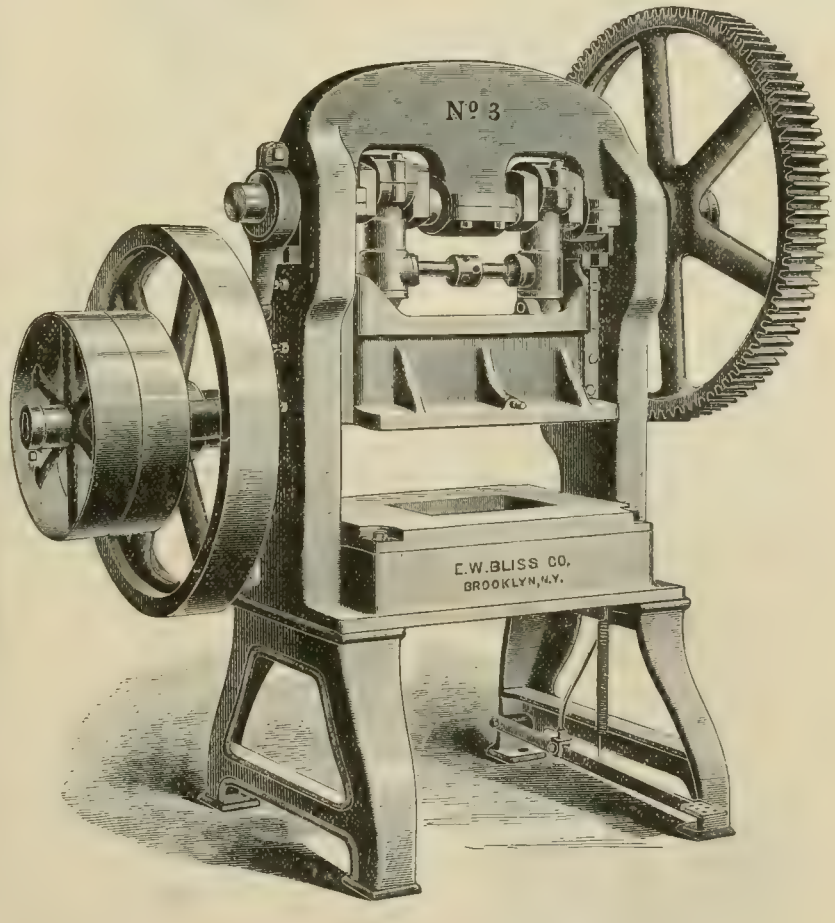
The bathroom is high and light, being provided with large skylights, over which shades are drawn in sunny weather. Thorough ventilation is secured by side lights which can be opened to their full extent, keeping the room cool at all times. Two large mirrors are fixed to the walls.

Mr. Williams looks at the matter primarily from a business point of view, believing that the bathing and washing facilities he gives his men will prove a good investment in the increased returns of work done. At the same time he regards it as a still wider question, affecting the community at large. His opinion on the subject is briefly put, in his own words, thus: "As it is acknowledged that habitual bathing prevents disease, and promotes health and morality, baths for working people affect all classes of society. Employers are, therefore, under moral obligations to supply such facilities, and health, decency and humanity demand it, because few opportunities for personal cleanliness are afforded to any but the privileged classes."

The arrangements are open to inspection at any time, and Mr. Williams has intimated his willingness to give any information desired in regard to the same, to those wishing to examine into his methods.

The Bliss Double Crank Press.

The accompanying cut shows a double crank press of new design made by the E. W. Bliss Company of Brooklyn, N. Y. The frame has been changed considerably in design and has been materially strengthened. The engraving also shows the new method of connecting the two pitmans by means of the rod shown, so as to enable the operator to quickly raise or lower the slide without danger of getting the two pitmans out of alignment with each other and with the guides. This press is specially adapted for operating large cutting, forming, perforating and bending dies. It can also be made without gearing and with overhanging frame instead of the straight uprights shown. Its most important dimensions are: 36 inches between the uprights; die space, up and down, 10 inches; adjustment, 2 inches; hight, 90 inches, and weight 5500 pounds.



THE BLISS DOUBLE CRANK PRESS.

Dr. Walter Kempster, who for six months past has been traveling abroad for the United States Government, for the study of cholera and its prevention, is completing his report. Its substance is that it is possible to keep the cholera from a city when the surrounding towns are tainted or to keep it from any house in an infected city, provided proper precautions are taken.

A new cable grip, invented by Major McNulty, chief engineer of the Broadway cable road, New York, has been tested on that road.

THE RETAIL STORE.

Boston Iron and Hardware Club.

The organization of this club, which has for some time been under way, has been perfected, and at a meeting held June 28 the constitution and by-laws were adopted and the following officers elected:

President,
S. A. BIGELOW, Bigelow & Dowse.
Vice-President,
E. A. HALEY, Dodge, Haley & Co.
Secretary,
F. H. BUTTS, Butts & Ordway.
Treasurer,
C. H. BRECK, Jos. Breck & Sons.

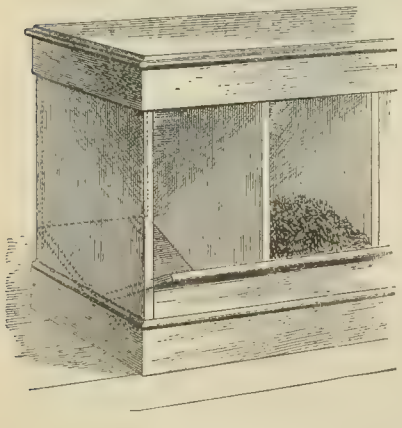
At the same meeting the following directors were also elected:

A. J. CHASE, Chase, Parker & Co.
LEON CARTER, Dana Hardware Company.
J. H. ROBBINS, Brooks, Baldwin & Robbins.
E. H. MANSFIELD, Woodrough, Mansfield & Co.

This club, while including all the Hardware houses of Boston, is not intended to be limited to merchants in that city, but is designed to cover the trade of the whole of New England. Its object is both to promote acquaintance among the membership and also to take action upon trade matters in which the merchants are mutually interested. It begins its operations under very favorable auspices, and its success is regarded as assured.

An Arrangement for Nails.

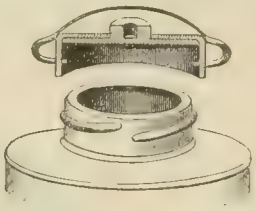
E. R. Smith, Pennville, Pa., has favored us with a sketch of Nail counter and bins, from which the accompanying cut has been made. The counter corresponds with others in the store in appearance, but has a hopper formed of boards slanting to the center near the floor. The board on the open side of the bins projects about 4 inches to admit of putting the scoop under when raking out Nails. Partitions are fitted in to form the several compartments, which are made large enough to hold from one to two kegs of Nails each.



An Arrangement for Nails.

Improved Glue-Can Top.

Russia Cement Company, Gloucester, Mass., and 95 Reade street, New York, are now packing Le Page's liquid glue and the various sizings made by them into tin cans having an improved top, as shown herewith. The improvement consists in the neck of the can being of tinned malleable iron with the cam sections cast on it, instead of tin with wire soldered on for cam sections. The wire points which project inside the cap require but a quarter turn to open or close the cover, while the cap and the eccentric shape of the cam draws the top down, making the vessel air tight. In the smaller packages, holes in the cap, surrounded by rubber, are provided for brushes, furnished with the packages, the holes so arranged that the brush can be adjusted to the quantity of glue in the can. The larger cans, for mechanics' use, have no brushes.



Improved Glue-Can Top.

The Lost Price-List.

The necessity of having a systematic arrangement of catalogues and price-lists was forcibly brought to the writer's notice during a short call at the store of a retail Hardware firm. At the time mentioned one of the partners was throwing out catalogues on the show case, while a prospective customer was waiting to know the price of some article not kept in stock. The books were taken, some from a cupboard behind the desk and some from a drawer under the counter. In a nervous, distracted and hurried manner the pile was gone over by the merchant two or three times in search of the one wanted, remarking the while that it was strange where that price-list had gone. He handed the customer a catalogue containing the same kind of goods, made by a different manufacturer than the one wanted, to keep him occupied, quietly called a clerk and sent him across the street to borrow the catalogue the merchant had been looking for, and betook himself to the back of the store, apparently to look for it there, but in reality to wait the return of the clerk. The conclusion the writer came to as he left the store was that, nine chances to one, the merchant would not take the order; while on the other hand, if the catalogues had been arranged and indexed, so that the class of goods and the various manufacturers of them could have been turned to in a moment, there would not have been much delay in closing the bargain.

Kitchen Novelties.

Matthai, Ingram & Co., Baltimore, Md., and 42 Cliff street, New York, are putting the above articles on the market as herewith shown. The Gem grater, Fig. 1, is described as being made entirely by machinery, having a retinned wrought-iron frame, and it is claimed to be strong, easily cleaned and durable. The seamless cup, Fig. 2, has a novel feature in the heavy spring handle riveted at the top and open at the bottom. The handle serves as a hook for attaching the cup to a belt, pail or other article. The galvanized soap dish, Fig 3, is provided with a drainer. The company advise us that they are turning out this article by means of improved machinery, and they claim that it meets the demand for a low priced durable soap dish.

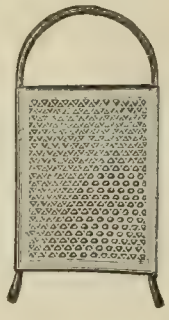


Fig. 1.—The Gem Grater.

Fig. 2.—Seamless Cup.

Fig. 3.—Galvanized Soap Dish.

The Iron Age Hardware Price Book F.*

This Price Book, which has just been received from the binders' hands, is larger, handsomer and more complete than the other *Iron Age* Price Books, A, B, C, D and F. The F Price Book is 8¼ x 11 inches in size, containing 556 pages of the celebrated Crane's heavy ledger paper, which is tough and strong, permitting frequent changes and erasures. The book is bound in the most substantial manner to withstand hard and constant usage, with covers of flexible seal grained leather. By means of the arrangement shown in Fig. 1, the index applies to every page, each page having an index tab (except 80 pages of supplement in the back of the book), thus permitting reference to any article at a single motion. This greatly facilitates the use of the book, avoiding the troublesome turning from page to page which is necessary in connection with other Price Books. Book F has been prepared with great care, giving a place, it is believed, for every article in the Hardware line, and ample space for recording prices. Sufficient space has also been provided for large lines of goods by allowing four pages to such goods, instead of two pages, as for lines of goods requiring less space. This is accomplished, as in **A X**, for example, by having the letter **A** on a short tab on the first of the two leaves, and **A X** on the tab of the second or lower leaf. The **A** on the first leaf is directly over the **A** on the lower leaf, so that the index reads **A X** whether looking at both leaves together or at the lower leaf only. The four rows of index tabs are printed in gold letters on black Russia leather, the tabs securely fastened on both sides of each page, making a handsome and durable index. Fig. 2 shows the index letters full size, and represents the eight first indices from each of the four rows of index. The book is arranged to keep a complete record of goods and prices on a single page, the width giving sufficient room, as shown in Fig. 1. The 80-page supplement at the back of the book is provided to give room for supplemental quotations, memoranda, tables, &c.

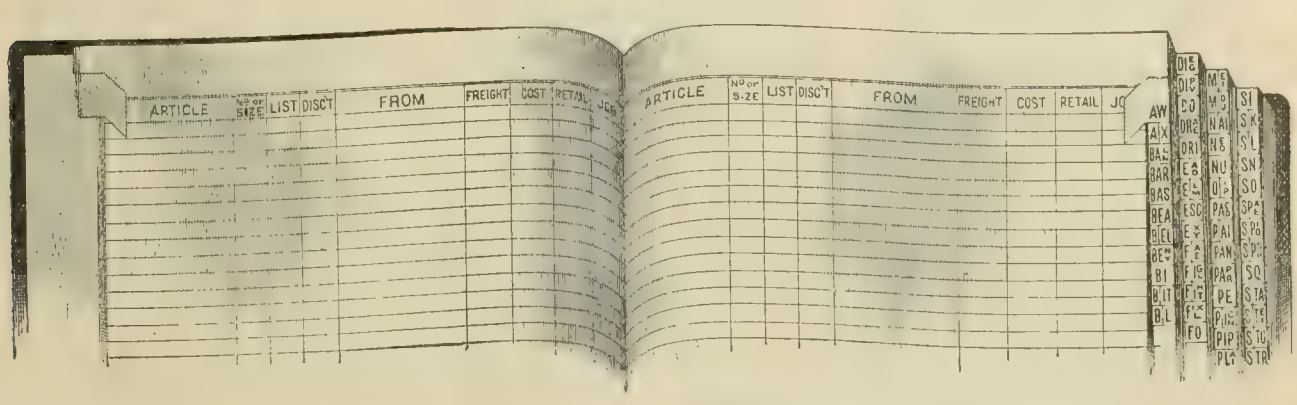

Fig. 1.—The Iron Age Hardware Price Book F.

AD	DIE C	ME I	SI
AN	DIP V	MO U	SK
AU	DO	NAI	SL
AW	DRA E	NE O	SN
AX	DRI	NU	SO
BAL N	E AD	O R	SPE A
BAR	EL M	PAC D	SPI O
BAS	ESC	PAI	SPR

Fig. 2.—Fac-simile of Indexing, Price Book F.

A special feature of the book, as also of Price Book E, is the arrangement of the index characters, which, while alphabetical, are arranged with special reference to the classification of Hardware goods, each index character giving the two or three first letters of the names of Hardware articles, as shown in Fig. 2, as for example :

For Augers	turn to	A U
" Parers, Apple	"	PAP R
" Saws	"	SAW
" Pumps or Punches	turn to	PUM N
" Bits	turn to	B I T
" Chisels or Chucks	turn to	CHI U
" Cutlery	turn to	CUT
" Cartridges	"	CAR
" Rules	"	RUB L
" Locks	"	L O
" Iron	"	IRO
" Irons	"	IR'S
" Shovels	"	SHO R
" Grindstones	"	GRI
" Stones	"	STO

The ease and convenience with which the book can be used is thus apparent. Special care has been taken to make the classification as indicated in the index correct and comprehensive, making provision for all Hardware articles and giving sufficient space for the keeping and recording of prices. It is thought that every strictly Hardware article has its first two or three letters given, thus permitting immediate reference to it by a single motion. It is, however, obvious if any articles are not directly designated by the index characters, that the index, being alphabetical in its arrangement, indicates the place where quotations on such articles should be recorded. The supplement, however, may be found useful for quotations on any outside goods which the Hardwareman may desire to keep prices on, while at the same time it may be used if necessary for an overflow of matter from the preceding pages, or to contain list prices or other matter relating to goods.

A 14-page pamphlet, containing a classification of the leading Hardware articles, is furnished with the Price Book, as an aid in suggesting the number of articles and the space required for each line of goods. The pamphlet will prove exceedingly useful, especially when first starting the Price Book. In connection with this Price Book a set of *The Iron Age* Standard Hardware Lists can be used with great advantage.

This Price Book is presented to the attention of Hardwaremen in the confidence that it will be found a most valuable aid in keeping track of the cost and selling prices of goods.

* "The Iron Age Hardware Price Book F," with multiple index, arranged by R. R. Williams, Hardware editor of *The Iron Age*. David Williams, publisher and bookseller, 96-102 Reade street, New York. Price, $7.50.

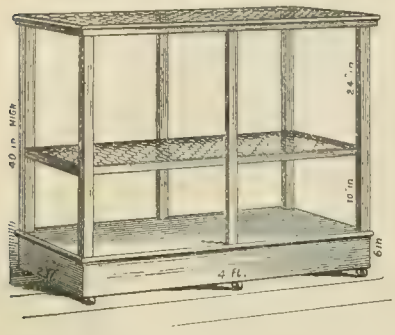
New Polishes.

The Tanite Company, Stroudsburg, Pa., and 161 Washington street, New York, have prepared a liquid polish which they state contains no injurious materials; and a polishing paste which they claim is also free from injurious ingredients, and is intended for the same uses as are met by the liquid polish. They also offer a knife polish in three different colors and qualities. This polish is in the form of dry powder, and is intended for use in rotary knife cleaning machines, on knife boards, &c. The manufacturers state that the powder is carefully graded, is even in texture and free from lumps, coarse grit, &c. Prices and size of packages are given under Notes on Prices.

GEORGE P. STOCKWELL, for many years engaged in the tin and stove business on Water street, Bridgeport, Conn., died at his residence a short time ago at the age of 80 years. He was one of the prosperous and successful business men of Bridgeport, and was one of the original trustees of the City Savings Bank of that place in 1859.

Fishing Rod Rack.

Reichley & Allison, York, Pa., have made for themselves a rack, as shown in the accompanying illustration, which they find very convenient, and which was constructed at a small outlay. The platform is

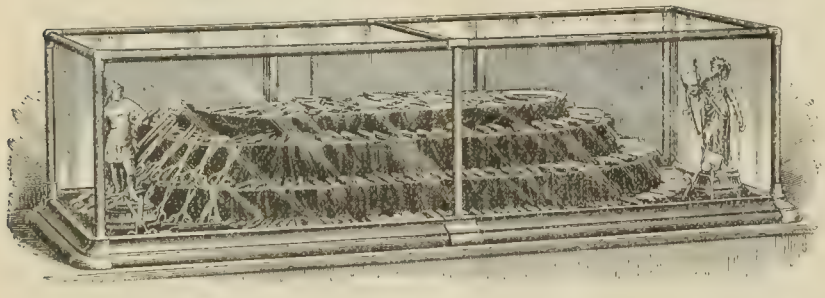


Fishing Rod Rack.

2 x 4 feet in size, 6 inches high, and is provided with six plate casters, so it may be wheeled to any part of the store or out of doors. There are six upright posts to which the frames are fastened, and on the frames are stretched pieces of 2-inch mesh poultry netting. The lower frame is 10 inches above the platform, and the upper frame 24 inches above the lower one, making the entire hight of the rack 40 inches. The number of Rods which the rack holds in comparison to its size is referred to as one of its advantages. The rack is also well adapted to holding Shovels, Hoes, Rakes, Forks, and a general variety of straight-handled goods.

Attractive Cutlery Case.

Ryan & Merrill, Miles City, Mont., have their Cutlery arranged in a case, as shown in the accompanying cut. The steps or shelves are circular in front, straight on the back, and are covered with material to show the goods to the best advantage. The shelving is left open at the back

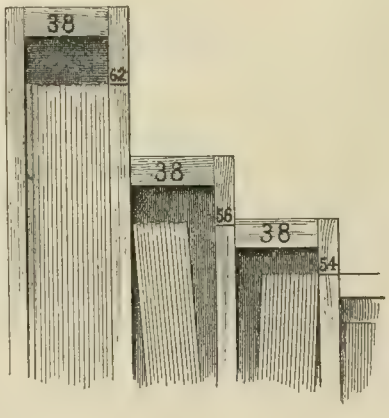


An Attractive Cutlery Case.

and provides a place for keeping stock. The center opening, which is the largest, is 19½ inches wide, 15 inches deep and 9 inches high, in which is kept the surplus stock of Pocket Knives. The original boxes are used, fixed with a staple and brass curtain ring to admit of drawing them out, the numbers being arranged in rotation. The space holds about 75 different styles of Knives. These are arranged in two rows, the rear row in five tiers deep and the outer row in seven tiers deep. The rear row is solid, while the outer row has spaces, so they may be slid one way or the other in order to get at those in the rear without disarranging the boxes in the front row. The spaces at each end of the shelving are 12 x 6 x 9 inches. At one end is kept the surplus stock of Shears, and at the other the surplus stock of Razors. The spaces will hold about six sizes of Shears and two dozen styles of Razors. The Shears are held in place on the steps by brass furniture tacks driven at the outer edge of the shelf. The statues fill in the corners of the case and add to the attractiveness of the display.

A Simple Glass Rack.

A simple and inexpensive Glass rack for holding large double or singe strength Glass can be made as shown in cut. It is made of old Glass boxes, from which the boards on one side are taken off, and are nailed together in



A Simple Glass Rack.

groups of from three to six boxes. The top and one edge of each box is painted white, the width of the Glass stenciled on the top, and the length on the side in black. A short mark is also made to show where the top of the Glass should come. C. D. Clapp, Toledo, Ohio, to whom we are indebted for the foregoing, states that with rack in use the boxes are permanent, that they do not slant or tip and that they take up but a small amount of room. He also remarks that it is the cheapest and most convenient rack he has ever used.

Novel Arrangement for Showcase.

In the establishment of Buehler, Bonbright & Co., 427 Market street, Philadelphia, Pa., showcases as shown in the accompanying illustrations, Figs. 1 and 2, are used. The feature of the arrangement is the weight which

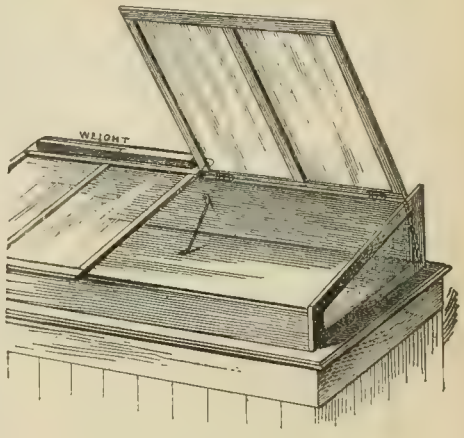


Fig. 1.—Novel Arrangement for Showcase.

counterbalances the lid of the case, holding it open when raised. The weight may be put on the top of the lid, as shown in the cuts, or hung underneath, as desired. It is desirable to have the weight distributed equally over the width of the sash to insure a distribution of the strain; the balance or weight may be neatly concealed in a box. Iron or lead is used for balances, and a base knob for a buffer. If the back of the case is designed to go close against the wall, the back can be sloped as in Fig. 2, to

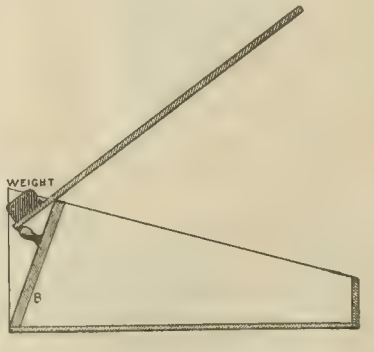

Fig. 2.—Weight and Buffer.

allow space for the balance, without sacrificing room on the bottom of the case. The weights vary with the size of the lid of the case, those in use being from 32 to 65 pounds, as the glass in the lids is heavy plate. This idea originated with Mr. Bonbright and a few of the cases were put in use. The arrangement proved so satisfactory that the system is being extended all over the store. The cases are arranged on the ledges under the shelving, also on counters, and are used for samples only. The store is 260 feet deep, facing on two streets, four stories high.

STOVE TRADE NOTES.

The Future of the Hot-Air Furnace.

BY A. W. GLESSNER,

President of the Excelsior Steel Furnace Company, Chicago, Ill.

THE SALE OF FURNACES.

If the sale of an article throughout a term of years can be considered a reliable index of its popularity, then the hot-air furnace must be a very popular article, for the demand for it has been constantly on the increase during the past five years. Each year has shown increased sales over the preceding year, and that increase in 1892 over 1891 must have been fully 25 per cent., and this in spite of the fiercest possible competition from other modes of heating. It is difficult to get at the actual number of furnaces sold in this country during 1892, but from statements made by different makers as to their outputs and from reports from our salesmen of the business done, it would seem that the aggregate number of furnaces sold in that year must have exceeded 65,000, and there are some makers who incline to place the figures considerably higher. A fairly accurate means of computation of the number of furnaces sold can be had from a knowledge of the amount of business done by the register makers, by far the larger portion of whose product is taken by the furnace dealers, and the business in registers in 1892 would indicate that upward of 600,000 were sold, and figuring that the furnace trade took two-thirds of this number and that on an average seven registers were used to a job these figures would indicate that nearly 60,000 furnace jobs were installed. These estimates are only approximate, but a tabulation of the furnaces made by the different makers would seem that the figures given are not too large.

In the East, and in many of the larger cities, the use of furnaces in smaller houses and flats has led to a decrease in the number of registers used to each job, and this has been further brought about by the installation of furnaces in old houses where first floor registers only are used.

THE DISTRIBUTION OF FURNACES.

At the recent meeting of the steam and hot-water fitters, held in this city, one of the leading makers of furnaces, and also a large producer of steam and hot-water boilers, had an exhibit of the latter forms of heating apparatus at the hotel where the fitters assembled, and the representative in charge was asked to state the effect had on the furnace branch of their business by the addition some years ago of hot-water and steam boilers to their line. His reply was that they had continued to sell more furnaces each year, and also found the sale of their steam and hot-water goods increasing, and this naturally brings us to a consideration of the distribution of hot-air furnaces. It is evident from an examination of the field that a marked change has come about within the past five years in the distribution of furnaces, and that while there is still a strong demand for high-grade furnaces to heat the residences built by the well to do in our various towns and cities, it is plain to note that a larger and larger proportion of houses costing $10,000 and over are being heated by hot water, but, as the number of houses of lesser cost are increasing in greater proportion than are those of the larger and more expensive class, the increase in the number of furnaces sold is partially accounted for. That hot water is taking a much greater proportion of the finer trade reflects not alone on hot air, but on steam as well, and the demand for hot water in the finer residences is a matter not alone of the preference for the hot-water heat over air or steam, but of the disposition to increase the cost of fine residences in our large cities by the addition of every new and expensive adjunct, and hot water has been a fad with not a few.

Again, in cities, an increasing number of blocks of houses are yearly put up by contractors for sale on easy terms, and have been equipped with furnaces; while flats without number are being erected, and tenants cannot be found unless some form of modern heating is provided, and furnace heat has been generally selected.

In the country, in towns and villages where, five years ago, a furnace was a novelty, and was to be found only in the church or public hall, the average house owner either has a furnace or is planning to have one as soon as he is able to afford it; and the new residences and buildings going up are provided with this form of heat.

It is also true that in many stores and also in office buildings of two and three stories in interior towns furnaces are being installed, and this movement has extended into the far West. Schoolhouses in Iowa and Nebraska are being supplied with furnace heat, and as far West as Utah furnaces are gradually coming into use, and the demand will grow as the knowledge of furnace heating and installation increases among the dealers.

Farmers are also alive to the benefits of a well-heated house, and have taken not a few furnaces of late; but a very important outlet for the production of furnaces is yet to be considered, and this is the introduction of the furnace into the working man's home in Philadelphia and elsewhere, which has resulted in the sale of thousands of furnaces of small size and yet of capacity equal to the damands made upon them. A model of such a home is to be seen on the Midway Plaisance at the World's Fair at Chicago; and while the cost of installing such a job is merely nominal, the results in the aggregate are such as to make a large sum.

(To be continued.)

ONE OF THE recent contracts closed by R. Campbell, 305 Pearl street, New York, was to heat with hot air a row of houses in which furnaces had failed to give satisfaction last winter. When the flues are rearranged Novelty Furnaces will be connected with them, as Mr. Campbell runs the line of Novelty goods made by the Abram Cox Stove Company, Philadelphia, and is confident that his plan of operations will prevent further complaint.

The Peoria Stove Works.

The catalogue just issued by the Culter & Proctor Stove Company, proprietors of the Peoria Stove Works, Peoria, Ill., is a comprehensive little volume, of a size which may be readily carried in the pocket, and is arranged in a manner convenient for reference. It is printed in two colors and bound in stiff board covers with gilt side title. In offering the volume to the trade the makers invite special attention, among others, to the Peoria Lexington range, made with six boiler holes and arranged for burning coal or wood. This stove has large flues, improved dampers, heavy linings, double covers, curved front grate of the shaking and dumping type, and full nickel trimmings. Under the same name the company offer a soft-coal range, embodying the modern features of construction and ornamentation. They also manufacture a soft-coal cook stove, for which many strong claims are made. Other goods include the Wabash and Woman's Rights cook stove, the Antelope range, made for burning wood only, and the Antelope four-hole cook stove. The heaters are represented by the Peoria, an all cast Todd for burning wood, and shown in a variety of styles and sizes; the Challenge, an attractive surface burner, having large radiating and ventilating flues extending from the bottom to the top and greatly increased heating surfaces; the Model Peoria, a hot blast ventilating parlor stove for soft coal; the Peoria Queen, a handsome square stove, which is being brought out to meet the demand for a substitute for stoves of the oak style; the Peoria hard-coal base-burner, with round fire pot, anti-clinker draw-center grate; the Peoria Oak, so constructed as to bring the fire pot as low down as possible; the Oak cottage, the Black Hawk, a neat cannon stove, made in several sizes; the Chief and the Empress. The catalogue closes with a list of stove repairs and the statement that the company carry in stock at all times a complete line of the best quality ground and plain hollow ware.

Ferncliff Stove Works.

We are indebted to F. L. Voegtly & Co., proprietors of the Ferncliff Stove Works of Allegheny City, Pa., for a copy of a neat catalogue and price list which they have just issued relating to their specialties. The little volume is made up of 38 pages of descriptive text and illustrations and is bound in green covers with side title wholly typographical in character. Reference is made to the new and attractive patterns which the company have introduced to the trade and to the facilities which they enjoy for manufacturing purposes. The early portion of the catalogue is devoted to the improved

Ferncliff range, a six-hole construction embodying the modern improvements and adapted for using coal or wood as a fuel. The makers state that each range is specially adapted for soft coal and can be had in a variety of styles and sizes. It is brought out this season with a new dress and has large flues, ample fire box with heavy cast linings and large top feed with register in the door. Following this construction we find the Fayette four-hole cook stove, made extra heavy in all its parts and designed for burning coal or wood and the Pansy, another member of this class and offered at a low price. Among the heaters the leading place is given to the Maybell, a very neat Franklin stove, possessing all the advantages of an open grate fire. The makers state that the manner of burning the fuel is the same as employed in the low down grates set in masonry, while economy and cleanliness are secured by means of an improved patent sliding blower. The stove is made in three sizes and is shown in the catalogue with the blower removed and also in position. The Mingo is another neat parlor stove of the Franklin type, which is made in three sizes. The Violet, a neat dwarf stove; the National cannon, made in two sizes and the Soho, a cheap globe stove, are some of the other goods to which attention is invited. A comprehensive price-list and some remarks about repairs complete the catalogue.

The Bridge & Beach Mfg. Company.

A handsome publication of 128 pages is that which reaches us from the Bridge & Beach Mfg. Company of St. Louis, Mo., Portland, Ore., and San Francisco, Cal. It contains illustrations of a fine assortment of ranges, cook stoves and heaters, among which are many new patterns for the year 1893. These include eight new lines, embracing 20 sizes of heating stoves, a new medium-priced coal range and a line of swing top box stoves, which are offered at a low price. In presenting this catalogue and price-list to the trade the manufacturers state that it contains not a single "duplicate or filed up pattern," and that all patterns are protected by letters patent, so that consumers handling their line of goods "control a specialty." The opening pages of the volume are devoted to general views of the company's works and several branches, remarks on breakages and freight overcharges on stoves and castings, suggestions with regard to the draft of chimneys in connection with which the stoves are employed and a telegraphic code for use in ordering goods by wire. Something like 20 pages are given up to ranges and cook stoves for burning wood as a fuel. These include the Grand Superior, Banner Mohawk and Home Mohawk ranges, and the Home Superior, Fern and Mohawk cooks, all of which are made in a variety of styles and sizes and embody the modern features of construction. The ornamentation in each instance is neat and effective, rendering the stove pleasing to the eye. Following these are a number of pages devoted to coal-burning constructions, made under names similar to those already given. Among the heating stoves we find the Superior Air Tight occupying the place of honor. This is in the nature of an oak stove made with single or double fire pot, large bailed ash pan, smoke fender, draw center wood grate and cone center coal grate. Under the name of Superior Oak the company offer a complete line of low-priced heaters adapted for burning coal or wood. The Elmo is a hard coal base burner made in two sizes, while the Lotus is a direct draft soft coal heater. A rather odd looking construction is the Pioneer, made with two boiler holes and a circular drum through which extends the smoke pipe in such a way as to heat the drum and render it serviceable as an oven. The Franklin is a very richly treated, all cast heater for wood, and is made in two sizes. A varied assortment of Todd, box, cottage parlor, cannon, globe and laundry stoves are also included. The catalogue concludes with a price-list of an extended nature, illustrations of water coils and couplings for use in connection with cook stoves and ranges, a long list of hollow ware, extras, &c., directions for ordering repairs, a variety of newspaper advertising cuts, and a comprehensive index. The catalogue is bound in a very neat style, the corners of the pages being rounded and the edges finished in a yellowish tint. The side title bears the dates 1837 and 1893, together with the name and various addresses of the company in black script letters on a straw colored ground.

A Fine Sample Room.

The Michigan Stove Company have entirely rearranged and redecorated the great sample room in their Chicago branch house on Clinton street, between Van Buren and Harrison streets. They have completely changed the immense line of cook stoves and ranges, putting samples of this year's new goods in all their places. Not an old cook stove or range is to be seen on the floor. The work of preparing for this complete overhauling of patterns has taken some three years. The style of castings and trimming adopted is very rich, surpassing in beauty anything previously accomplished by this radically progressive company. Scroll work predominates in the ornamention, but the scrolls are large, requiring fine molding to bring out their surfaces smoothly. The immense variety of the company's productions in this line is shown by the fact that 125 samples are displayed, and even this does not comprise the entire assortment, as there was not room enough to sample everything. The cook stoves and ranges occupy the main portion of the sample room, arranged in four long rows. Heaters extend along the side, ranged in the order of their sizes, and overflow in a side extension of the room in the rear.

A recess in the center, projecting into the warehouse, contains more ranges and a line of steel ranges surmounted by an elegant canopy extending the full length of three ranges in an unbroken stretch. The salesmen's desks have been removed to the rear of the sample room, where a row of windows gives them an abundance of light. A heavy brass railing separates this space from the rest of the room. The change from their former dark quarters in the recess is keenly appreciated by the genial travelers.

An original Detroit cook stove, made by Jeremiah Dwyer & Co. in 1862, before the incorporation of any of the Detroit stove companies, occupies a conspicuous position among the samples. It is a fine-looking stove, and was in its day a very popular stove in Western kitchens. Beside it stands a specimen of the first anthracite self-feeding stove in America, invented by Dr. Nott, president of Union College, Schenectady, N. Y., from 1804 to 1866. This identical stove was placed in the experimenting room of the college early in the present century, and is still in a good state of preservation.

The walls of the sample room are colored a dreamy tint, suggestive of pea green, which harmonizes with the black and nickel of the stoves very well. It was the suggestion of F. D. Millet, the artist in charge of the World's Fair color department.

ODD PLATES.

The Auburn Stove Foundry Company of Auburn, Maine, have just brought out an attractive wood parlor stove known as the Falmouth. It is made in two sizes, is of graceful proportions and ornamental in design. The coal parlor stove which the company placed upon the market last year and the Royal Falmouth and Stanley ranges met with a large sale and are constantly growing in popularity. The company are keeping a sharp eye on the market and continually striving, by means of new patterns and improvements, to cater to the public demand. That they have been successful in accomplishing this end is evidenced from the continually increasing sales recorded for their goods. The company state that the outlook for the coming season is very bright, and that although business this year in general promises to be very quiet, they expect to enjoy a larger volume of trade than ever before. Another indication of the company's prosperity is found in the fact that a semi-annual dividend of 3 per cent. was declared a short time ago, payable on the 1st of July.

J. J. Wolf of Cleveland, Ohio, is representing the Victor Stove Company of Salem, Ohio, in Indiana, Illinois and Michigan, and showing a new open Franklin and some new cooks and ranges. The company have not been represented by Louis Waldecker of St. Louis, Mo., since the middle of March, when their business connection was severed.

"The Alaska Stove Hardware" is the title of an eight-page circular which has just been distributed to the trade by the Troy Nickel Works, Troy, N. Y. The design on the front cover is exceedingly frigid in character, and has imbedded in its center a representation of a boltless stove knob and the words "Always cold." The pages of the circular show illustrations of Alaska fire sets, parlor sets, pokers, lifters, shovels, loop handles, &c., finished in nickel plate and of a design in keeping with the high class of goods turned out by the concern named.

The Cabinet gasoline ranges made by the Dangler Stove & Mfg. Company, Cleveland, Ohio, have received an appreciative welcome at the hands of the public, while the Surprise, New Success and Dangler Process stoves have all had a liberal patronage. The low Juniors are consumed in never-diminishing quantities every season, and the advent of the high Junior only swells the number.

The Crown furnace and Crown steam-heater are constructions to which the manufacturers, March-Brownback Stove Company, Pottstown, Pa., refer to with no little pride. They state that the Crown furnace is made of the best quality cast iron and wrought steel and is gas and

dust tight. The Crown steam-heater is strongly built and is economical in the use of fuel. The company have issued a special heater catalogue, a copy of which will be sent to any one who may be sufficiently interested to write for it.

A. Weiskittel & Son, Baltimore, Md., have issued a neat folder relating to some of the fire place heaters which they manufacture. The list includes the Favorite, Ideal, Comfort and the Fire King. The principal features of these heaters are pointed out, while several testimonial letters show their popularity in the trade.

The Joliet Stove Works of Joliet, Ill., are pushing with a great deal of enterprise the sale of Moore's air-tight heater, the features embodied in which are fully covered by letters patent. The makers state that it is practically a small furnace surrounded by an open casing. The fire pot, dome and air flues are arranged in much the same manner as in the most approved furnace construction. Since this heater has been introduced to the trade a large number have been sold and it is steadily growing in popularity.

The Bussey-McLeod Foundry, Troy, which shut down for repairs, started again Thursday, July 13, after about a week's idleness. They report business about the same as at this time last year.

The Burrell-Johnson Iron Company, Limited, Yarmouth, N. S., have issued a large circular showing the Model Grand six-hole range, fitted with reservoir, elevated hot closets and low warming closets. This range is referred to as being well made in all its parts, embodies the modern features and is ornamented in an attractive style. The range is well known to the trade of the United States as a product of the foundry of the Spicer Stove Company of Providence, R. I., although the concern named above are sole manufacturers for the Dominion of Canada. Surrounding the picture of the stove on the circular referred to are a number of testimonial letters from some of those who have used the Model Grand and who testify in flattering terms to the satisfaction which it has given.

A recent issue of the Baltimore *Sun* says that the plant of the Union Foundry & Stove Works of Frederick, Md., was recently sold by the trustees to F. M. Fauble.

The New Jersey Lamp & Bronze Works of New Brunswick, N. J., of which Ralph W. Booth, of the place named, is manager, and Henry Gleason, of 106 Beekman street, is New York agent, send us a copy of an interesting catalogue which they have issued showing the line of stove figures and urns manufactured by them. The printing is in various colors, in imitation of the style in which the different classes of goods are made. The figures cover a wide range, each being numbered, thus facilitating ordering and reducing liability to error to a minimum.

The Weir Stove Company of Weir Village, near Taunton, Mass., closed their works on the morning of July 1 and remained shut down until Wednesday, the 19th inst. During the interval a number of necessary repairs were made and such changes incorporated as the business of the company warranted.

M. M. Ewing is now on the road representing the Howard Stove Company, Beaver Falls, Pa., and showing the trade a new pouch-feed flat top cook stove, made in two sizes, 8 and 9 inch. The Howard range has been redressed for this year, the new oven door having a nickel-plated panel with a tile and new set of feet with a skirt. It also has a top cresting, which contributes a pretty effect as well as being useful.

Burdett, Smith & Co.'s foundry at Troy, N. Y., which suspended operations Thursday, June 29, for the purpose of allowing their employees a vacation and for making necessary annual repairs, resumed operations Friday, July 14.

James Boyle of James Boyle & Co., Salem, Ohio, when in Chicago at the meeting of the National Association, found the fair more interesting than the stove convention and spent most of the week enjoying the sights and storing up ideas for the production of additions to the line of stoves of which the Perfect Oak is now a leader.

The Excelsior Steel Furnace Company of 110–114 South Jefferson street, Chicago, Ill., have issued a couple of leaflets, one of which is entitled "First Cost and Final Cost," while the other is headed "What You Get When You Buy an Excelsior Steel Furnace." The construction named is described in such a way as to emphasize the special features embodied, while the advantages of the furnace are carefully pointed out. The company state that it is easy to figure the first cost of a furnace, but not so easy to figure the final cost. In making their heaters they have endeavored to render as easy as possible the work of the furnace setter, and they state that in the fitting and construction of their goods they believe they save the dealer several dollars over the cost of setting furnaces of other makers. One of the special advantages to dealers handling the Excelsior steel furnaces is claimed to be the fact that they can obtain of one house everything needed in the way of furnace fittings.

A visit to the Standard Lighting Company of Cleveland, Ohio, is sure to receive a cordial welcome and the accumulation of much interesting history of the growth of the use of gasoline stoves all through the country, and how the New Process vapor stoves increase in popularity as they become more widely introduced.

Grange Sard, vice-president of Rathbone, Sard & Co., Albany, N. Y., has returned from a vacation at Magnolia, Mass., and Colonel Bowditch of the same concern from Northeast Harbor, Maine.

John T. Perry of the Perry Stove Company says that from the present indications work will continue without interruption until later in the fall than usual, a large number of men being employed. It is the opinion generally among the stove men in that section that the manufacturers of heating goods will tide over the financial stringency safely, and that the outlook will be brighter in a short time. A boom is liable to succeed the present depression.

The Committee of Awards on Floats in the Fourth of July celebration at Troy, N. Y., awarded William E. Sandham, the Troy agent of Rathbone, Sard & Co., Albany, N. Y., the prize for the most meritorious stove display of the day. Mr. Sandham feels much elated over this result. A diploma was awarded to George H. Cole of Troy for his gasoline stove exhibit, and one to the Andes Stove Company for the most artistic float representing the stove industry. The Sandham display of Acorn stoves was a beautiful one, containing three ranges and two parlor stoves, all handsomely nickeled, making a dazzling array.

J. Woodruff & Sons, Salem, Ohio, have some new attractions to their line of stoves and ranges that will catch the people's fancy when displayed by the dealers in the fall.

The Leibrandt & McDowell Stove Co., Philadelphia, are not adding to their line of goods this season, and beyond one or two immaterial changes the line will be the same as last year. Their supplementary catalogue for the season covers their Victor Cook, Target, Prompt, Tayloe, Cozy, Midway, Ironsides, New Ironsides, Our Friend, Farmer Girl and Farmer Boy cooking stoves and ranges, their hotel range, broiler, and a line of heating stoves including the Olinda, Envoy, Radnor, New Hot Air Elm, New Vulcan, Tyrone, Luna, Opal Ray and others well known to the trade. The season will find them with a good stock on hand and present indications point to a good business.

E. A. Cress, lately with the Raymond & Campbell Mfg. Company of Middletown, Pa., is now representing the Leibrandt & McDowell Stove Company, and is calling on the trade in the interests of his new company.

The Union Furnace Company, at 30 Myrtle avenue, Cleveland, Ohio, are located in the residence section of the city and make a specialty of the furnaces turned out by the Kernan Furnace Company of Utica, N. Y. They have sold, in and around the city, between 700 and 800 of these furnaces and claim that last winter brought them no complaints from their work, but many inquiries for goods for next fall.

A. F. Wolf, who at one time was a stove manufacturer, recently made a visit to the scene of his early labors, now run by the Howard Stove Company, at Beaver Falls, Pa. Mr. Wolf is engaged in raising blooded horses at New Castle, Ky.

A good season has been experienced by the Schneider & Trenkamp Company of Cleveland, Ohio, on the line of reliable gasoline goods and all of the attending necessary equipments. Larger stoves and the best grade have been most popular this year, and their use extends longer into the cold months each year, owing to their convenience and excellent service.

Some new goods are all ready for shipment by the Paisley Stove Company, Beaver Falls, Pa. The Famous range has six holes and is made right or left hand, with pouch feed, cast linings and skirt and a nickle-plated oven panel with tile decoration. This range is made in three sizes, 7, 8 and 9 inches, all sizes having a handsome top shelf. The Home Rule is another range, in two sizes, 8-20 and 9-20, with high shelf, high closet and enameled reservoir, and of design and finish worthy of a high-grade range.

The Michigan Stove Company have issued from their Chicago office a large card intened to be hung up in the store of the hardware dealer handling the company's goods. The card carries in conspicuous form a *fac-simile* of the guarantee which is given with every Garland stove or range sold by the makers. This guarantee is manifestly of

such interest to the trade at large that we quote the text of it below:

KNOW ALL MEN BY THESE PRESENTS:

That this Garland is sold with the absolute guarantee of being the finest and best construction of its kind made for the price asked. It is guaranteed to operate in all cases under necessary conditions when the directions for using are followed.

In case of any imperfections in material or workmanship, the seller and manufacturer agree to make the same good.

Every feature of economy, durability or convenience that an experience of 20 years has shown to be desirable, will be found in the Garland line.

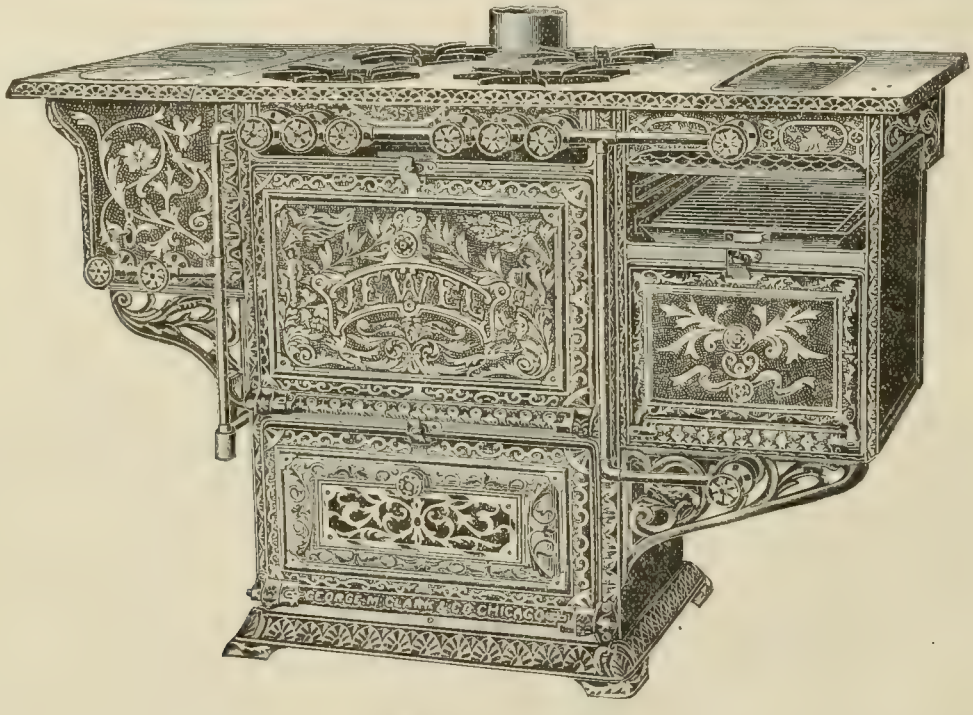
Garlands are the only line of stoves and ranges in the world made from a mixture of the best and highest grades of iron and aluminum, which mixture adds strength, prevents cracking, blow holes and other imperfections, and is a benefit to iron in every way.

The guarantee is signed by the agent or agents, handling Garland goods, and in addition the guarantee carries the trade-mark seal and signatures of the officers of the Michigan Stove Company.

JAS. L. HAIGHT, the present superintendent of manufacture of the MacKellar Foundry Facing & Supply Company, Quincy, Ill., has been in the facing business for many years, and is consequently well fitted for the position to which he has just been appointed. His long experience will go far toward making the MacKellar facings even more popular than they have been in the past. Mr. Haight succeeds W. H. MacKellar, whose resignation as superintendent was accepted at the directors' meeting held on May 1.

The Lehigh Stove & Mfg. Company,

with office and foundry at Lehighton, Carbon County, Pa., have just issued from the press a very neat catalogue, illustrating their leading lines of cook stoves and heaters. In presenting it to the trade, attention is invited to the additions and alterations which have been made in the Lehigh line of goods since the last catalogue was brought out. The Lehigh range is a very attractive, well proportioned stove, having six boiler holes, large oven, triplex grate, outside oven shelf, large flues, patent oven-door opener, and other features of convenience. It is made in several sizes and styles, and is intended for using hard coal, soft coal or wood as a fuel. The Lehigh Valley is another member of this class and is made in four sizes, several of which are shown in the catalogue. A well constructed five-hole range is offered the trade under the name Lehigh, while under the name Gem Lehigh is another range of the same general variety. The cook stoves are represented by the New Gold Medal, for coal or wood, and the Miners' Pride, a stove intended for the coal regions, where, fuel being cheap, a large fire box is essential. The heaters are represented with the Lehigh square base burner occupying the place of honor. Its constructive features include large fire back and anti-clinker grate, with center dump, capacious ash pan and desirous features of ventilation. The stove is of graceful outline and is ornamented in a way to please the eye. The Upper Lehigh, made in three sizes; the Fairy Lehigh, a cheap direct draft parlor stove, also made in three sizes; the Royal Lehigh, a square stove with perforated cast iron body and round inside steel body lined with brick; the Lehigh Franklin, the Maple, an all-cast surface burner; the Clearfield, a first-class cannon stove, and the Trix, a low-priced heater, are also considered. The catalogue closes with brief reference to the Lehigh Paste Polish, a list of stoves for which repairs can be furnished and a price-list of trimmings.



New Jewel Gas Range.

A New Jewel Gas Range.

A new series of gas ranges has just been brought out by George M. Clark & Co. of Chicago. There are four ranges in the series, and they are intended to cover the requirements of a family of any size. The largest of these ranges is herewith illustrated. This construction has eight cooking holes. Looking at the range from the front, the water heater is on the left. It has a large pipe coil with a double burner below. The heat passing about the coil is further utilized by two cooking holes at the top. The center of the range has two compartments, the upper one being a baking oven 18 x 16 by 11½ inches, and the lower one a roasting or broiling oven 18 x 17 by 9½ inches. On the right is a peculiar arrangement, which is decidedly novel and would seem to be very desirable. There is a baking plate for cakes on the top, the opening being 19½ x 9 inches, which can also be covered by a grate, making the equivalent of two cooking holes. The burner below it is a reversible burner with three caps, which is used with the caps up for baking cakes or cooking. A crank on the end of the burner reverses it, and with the caps under it is used for heating a small broiling oven below which is 12½ x 17 x 4 inches in size and is just suitable for broiling steaks or other meats for breakfast. Below this broiling chamber is a warming oven 12 x 17 x 8 inches in size, heated with a long slotted burner, which burns but a small quantity of gas and keeps food warm much more satisfactorily than the large baking oven. The burners for the water heater and the large oven are fitted with pilot lights. The two rear top burners are fitted with the Jewel Argand, one front burner with the Jewel Argand and a larger one outside of it, and another front burner with the Jewel Argand and a simmering burner in the center.

The doors are all of the drop pattern and balanced by spring hinges.

The other ranges of this series differ in some details from the one described, but are finished in precisely the same way. One has the small broiling chamber and warming oven, but no water heater. The second has a water heater, but omits the small broiling chamber and warming oven. The fourth is the plain center of the range without both the water heater and the small broiling chamber, &c.

Externally, these ranges are superb specimens of fine molding. The doors and other panels in front are finished in leaf work, exquisitely carved, with the high surfaces buffed, making a very pretty contrast to the plain black of the background. Nickel has not been used too freely in decorating. The sides are finished as well as the front, so that the range does not suffer by inspection from any but a front point of view.

TRADE REPORT.

The Iron Market.

The financial difficulties still dominate the situation and nine out of ten large concerns are expending more energy and thought over their collections than they are over new business. The need of money is bringing into the markets a good many bargains and an unusually heavy proportion of the total purchases are covered in that way.

The Iron scale is still unsettled, but it is the general belief that an agreement will be reached by the time repairs have been completed and the mills are ready for operation. The mills, however, are nearly all assuming an aggressive attitude, and as there is nothing to indicate a better demand, it is difficult to see how they all can keep their doors open. Lower prices than those now ruling will not increase the volume of business, yet that feature appears to be more susceptible of development than any other.

Pig Iron.—The New York market is exceedingly dull and there are numerous reports of concessions to effect sales. The very great reduction in the output may have some influence upon the market soon, particularly since it is known that a further restriction has gone on since the beginning of the month. We quote Northern brands at $14.50 @ $15 for No. 1; $13.75 @ $14.50 for No. 2 at tidewater. Southern Iron, same delivery, $13.75 @ $14.50 for No. 1; $12.50 @ $13.50 for No. 2; $12 @ $12.25 for No. 3; $12.25 @ $12.50 for No. 2 Soft, and $12.75 @ $13.25 for No. 1 Soft.

Transactions in the Philadelphia market have been few and unimportant during the past two or three weeks, and at the moment there is nothing in sight likely to bring about any particular increase in the volume of business. The continuous curtailment of production, however, enables holders to keep the market pretty well in hand, so that prices are steady and liable to develop firmness as soon as there is anything like an ordinarily good demand. General quotations are about as follows for Philadelphia deliveries, and from 20¢ to 30¢ less for Southern Irons at points accessible by water:

American Scotch, No. 1X...	$16.00	@ $16.50
American Scotch, No. 2X...	15.00	@ 15.50

At Chicago a few more large concerns have placed season contracts for local Coke Iron, but the general condition of trade is very bad. Consumers are not only requesting shipments deferred, but are asking for extensions of time on what they have bought. Inquiries for Southern Coke are confined to small lots of 100 tons and less, but rather more of these have been received the past week than for some time previous. Country trade seems inclined to purchase, now that prices are so low. A point has been reached, however, which is testing the endurance of makers, and they are beginning to withdraw extremely low quotations. Our quotations give the ring of regular asking prices, Chicago delivery, but they are subjected to concession, as usual of late, for immediate delivery.

Lake Superior Charcoal.....	$16.00 @	$16.25
Local Coke Foundry, No. 1...	13.50 @	14.00
Local Coke Foundry, No. 2...	12.65 @	13.00
Local Coke Foundry, No. 3...	12.75 @	13.00
Local Scotch.....	14.00 @	15.00

There cannot be said to be any improvement in Southern Pig Iron. On the contrary, some sales have been made for spot cash and prompt shipment at concessions of about 25¢ from quotations, which we do not change, for these cash sales are few and exceptional. The volume of business in the aggregate is not large and the demand is mainly for single car lots, although there have been several sales reaching 500 tons. Nearly all varieties of Iron have sold to some extent, but the chief demand is for No. 2 Foundry. Requests to postpone deliveries on maturity contracts continue to be the rule. Quotations are as follows:

Foundry.

Southern Coke, No. 1.	$13.00 @	$13. 5
Southern Coke, No. 2.....	11.50 @	11.75
Southern Coke, No. 3.....	11.00 @	11.25
Ohio Soft Stone Coal, No. 1....	16.00 @	16.25
Ohio Soft Stone Coal, No. 2....	15.00 @	15.25
Lake Superior Coke No. 1.....	15.00 @	15.25
Lake Superior Coke No. 2.....	14.00 @	14.25
Hanging Rock Charcoal, No. 1..	18.50 @	19.00
Hanging Rock Charcoal, No. 2..	17.50 @	18.00
Tennessee and Alabama Charcoal, No. 1.....	15.00 @	15.50
Tennessee and Alabama Charcoal, No. 2.....	14.00 @	14.50

Metal Market.

Copper.—No change in the general situation has taken place during the past week. Purchases by home consumers seem rather below the average, and export movement, drawing the line at deliveries on old contracts and consignments to Europe in expectation of a better market there than on this side of the Atlantic, has been comparatively light. On sales in the regular way the trading basis has been 10¼¢ for Lake Superior Ingot, 10¼¢ for Electrolytic, and 9⅞¢ @ 10¢ for Common Casting Stock. Small parcels of some few brands realized a fraction more, but only in strictly exceptional instances.

Pig Tin.—The market has been a peculiar one in certain respects, reflecting rather severe depression from the weight of excessively burdensome holdings in some quarters; "bear" manipulation that served to aggravate matters for a time and subsequently a sharp upward turn in prices so engineered as to create the impression that the leading holders have not only secured very good control but are in a position to maintain the advantage as long as the duty of 4¢ ℔ lb keeps Tin from coming to this country in any considerable quantity. Wednesday's prices on 'change were 18.90¢ bid, 19.10¢ asked for spot; 19.12¢ asked for July and 19.60¢ for August delivery.

Pig Lead.—Prices have advanced somewhat and the market shows decided recovery in tone from the depression that prevailed during the early part of the period covered by last week's review. Selling prices at the close were 3.60¢ @ 3.65¢ for spot stock and early shipments, and 3.70¢ for late shipments.

Spelter.— In the market for this metal there has been no change whatever. Sales still run light and the demand drags in a wearisome manner, while the offering indicates that more or less accumulation of stock in smelters' hands has taken place this month. Ordinarily Western brands, however, are not offered openly at less than 4.20¢, landed here, but the appearances are that offers of 4.15¢ for near future shipments would be accepted.

Antimony. — Jobbing distribution has been fair, but the movement otherwise continues light and the demand is slow. Prices are easy at 9⅞¢ for Hallett's, 10½¢ @ 10¼¢ for L X, and 10½¢ for Cookson's on the spot.

Tin Plate.—At intervals there has been rather better buying of ordinary Bessemer Coke Plates, chiefly by canners of vegetables and the trade demand for other varieties has shown slight improvement. However, the change has not been broad or general enough to have any pronounced effect upon the market, and close buyers who are in a position to pay prompt cash doubtless secure quite as good bargains as have been picked up at any time during the past month or six weeks. Future shipments continue in neglect, with hardly any interest displayed, except in special sizes, and nothing outside of common-place buying there.

Press dispatches, which will be received with considerable skepticism, announce that the Iron Mountain vein, at Iron Mountain, Mo., is virtually exhausted.

Chicago Report.

Scrap.—The following buying prices are still quoted by dealers, but many of them are refusing to purchase any stock whatever, as it is impossible for them to dispose of it to consumers.

	Per net ton.	Per lb
No. 1 Wrought Scrap	$10.00	....
Machinery Cast	7.50	....
Malleable Cast	7.00	....

Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

THE SHEPARD HARDWARE COMPANY, with temporary offices at 67 and 69 Forest avenue, Buffalo, N. Y., issue a circular to the trade respecting the interference with their business caused by the destruction of their works by fire. The circular is headed with a half-tone engraving of the ruins of their factory, and below is the line "The above cut explains why we cannot execute orders promptly." They say in their circular that they are declining orders owing to the destruction of their works and office, their stock not only being burned but also the machinery, patterns, follow boards, &c. Still they hope to make shipments before November or December next. Their pattern makers are now at work, so that their customers can rely on getting Lightning Ice Cream Freezers and other goods of their manufacture for the spring season of 1894. They add that they have no repairs for Freezers on hand, but they hope within the course of a few months to be able to furnish them. The Shepard Hardware Company have not yet decided when and where they will rebuild, but will advise the trade as soon as possible.

CONDITION OF THE

Hardware Trade.

JULY is generally regarded as, perhaps, the dullest month in the year, when trade is characterized by a midsummer quietness. The present month promises to be no exception. Manufacturers are, many of them, shut down for repairs or improvements and some of them to avoid undue accumulation of stocks. Many others whose works are in operation are curtailing their production and refraining from running to their full capacity. A disposition prevails to avoid piling up stock, and it appears probable that during the present month the amount of goods manufactured will be considerably below the average. Manufacturers are induced to adopt this course on account of the present moderate demand and the uncertainty as to when trade may be expected to assume its regular volume, and also on account of the present financial stringency, which induces conservative action on their part. At the same time, it should be borne in mind that there is a considerable amount of business doing, and in some lines manufacturers have not much more than caught up with their orders. It appears evident, looking over the trade of the past six months, that its volume in many lines compares well with that of the same period in other years, and some manufacturers report it as having been exceptionally good, notwithstanding the financial disturbance. With the turn of the half-year but few changes in prices are announced, and while the market is not strong and some manufacturers would be willing to accept orders at slight concessions from former prices, quotations are on the whole well sustained.

Advices from Chicago.—The financial situation has improved somewhat, making collections better, but trade otherwise is discouragingly dull. The statement may be an exaggeration of the condition of business, but some houses report their daily orders for the past week or two hardly balancing their daily expenses. They look forward to a heavy volume of business later to compensate for the dullness now, but think it may be necessary to wait until crop prospects are more settled. World's Fair visitors are becoming more numerous in the Hardware trade, but they are buying very little, evidently coming here for recreation alone. Prices show no material change, but there appears to be a disposition to make concessions on Tin Plate, and prices are a little easy on Coke brands.

Notes on Prices.

Cut Nails.—The Cut Nail market is inactive and many of the mills are shut down. Several of them are, however, in operation. Prices are without change on a basis of $1.05 for carload lots at mill, which, however, would doubtless be slightly shaded in some cases under pressure. Small lots of either Iron or Steel Nails from store in New York are quoted regularly at about $1.30.

Advices from Chicago.—Cut Steel Nails are rather quiet in this particular locality, but good orders are being received from distant points, showing that trade is better there than here. Notwithstanding this, efforts are being made by outside manufacturers to force local trade, and reports are current of concessions being offered. The claim is made that such concessions are based on averages, the intention being to dispose of accumulations of small Nails. Regular quotations here for factory lots are continued at $1.20 to $1.25. Jobbers are quoting small lots from stock at $1.30 in a regular way and $1.25 for quantities.

Wire Nails.—Business in Wire Nails is very light. Mills are generally shut down in accordance with the understanding reached a month ago. Their disposition is to pursue a conservative course and avoid the accumulation of stock in the hope that the diminished production and possible scarcity, if business should improve, would enable them to obtain better prices. The quotation continues $1.35 for carload lots at mill. Small lots from store in New York are held at about the usual advance.

Advices from Chicago.—Although the shutdown of the factories has lasted but little more than a week, manufacturers' stocks have already been broken, and some of them are buying from the others in order to fill contracts standing on their books. Inquiries are also being received from large buyers for good quantities. Sales have therefore improved to some extent since our last report, and the future seems more hopeful. Factory lots are quoted at $1.45, Chicago, and this is now claimed to be the lowest price offered by standard mills. Local jobbers find their business affected by the pronounced dullness in building circles, but have made no change in their prices, which are $1.60 regular and $1.55 for quantities.

Barb Wire.—The Barb-Wire market is decidedly sluggish, and very little is doing. Prices are unchanged at $2.45 to $2.50 for carload lots at mill.

Advices from Chicago.—The movement from factories is very light and new orders have almost ceased. The mills, however, will remain shut down for some time, so that the dullness of trade can easily be borne for the present. Quotations continue at $2.15 for carload lots of Painted and $2.55 for Galvanized. Jobbers report their trade extremely quiet, with prices unchanged at $2.30 and $2.70, respectively.

Cordage.—The Cordage market gives indications of a slight weakness and prices are a shade lower than at our last report. The market is represented by the following quotation for round

lots, f.o.b. factory or New York, subject to a cash discount of 1½ per cent.:

	Basis.
Manila	$0.08¼ @ $0.08½
Sisal	.07 @ .07⅛
New Zealand	.06⅛ @ .06¾

Binder Twine is moving freely and without important change in price.

The Smokeless Frying Pan.—W. E. Beveridge, 305 South Sharp street, Baltimore, is manufacturing this article. It is sold from the following list, which is subject to a discount of 33⅓ per cent. in dozen lots.

No. 8	$1.00
No. 9	1.15
No. 10	1.25

Clothes Wringers.—We give below the new list of the Lovell Mfg. Company, Erie, Pa., for whom William H. Quinn & Co., 103 Chambers street, New York, are agents. This list, which is contained in their catalogue, covers their complete line of Clothes Wringers, to which numerous additions have recently been made, including a number of goods of similar pattern to those of other manufacturers with which the trade are familiar. A very complete line is thus being manufactured by the company, who make the point that they are now putting on the market a variety which covers all the requirements of the trade, so that merchants can obtain their full supply of them. Their list is as follows and is subject to a discount of 12½ per cent., terms f.o.b. Erie, 60 days, or 2 per cent. discount for cash in 10 days:

Happy Thought Wringer.

Patent Roller Bearings. Regular Width Swing Clamps.

No. 110, 10 x 1¾	rolls, per doz		$32.00

Glass.—The condition of the Glass trade is usually one of quiet at this season of the year, and the present time shows no exception to the rule. Conditions are not favorable for a large volume of business and orders are small, covering only present necessities. Considerable attention is being paid to the collection of accounts, and the financial standing of customers is carefully scrutinized before goods are shipped. Such conservative action on the part of both the retailer and jobber cannot fail to bring about good results, as small stocks and unimpaired credit will give an impetus to trade when financial confidence is restored. The trouble in making collections to meet immediate obligations has not deranged prices, and goods are billed at regular quotations. It is reported that the wage committee of

Glass workers and manufacturers were to meet in New York July 12 to consider the scale of wages for the coming fire. The impression prevails that the plants will make an early start if a satisfactory agreement is arrived at. Quotations on Glass remain unchanged, as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—Old Rubber appears to be in better demand than other "old junk." Rubber shoes can be utilized for the greatest number of purposes and are, therefore, most sought for. Scarcity of funds for legitimate business purposes has affected the Old Rubber market, causing somewhat lower quotations on some grades of Rubber. That there is a market for these goods at quoted prices is a matter for congratulation, considering the present financial situation. The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, ton lots, ℔ lb.	@	$0.03¼
Rubber Shoes, carloads ℔ lb.	@	.03⅛
Rubber shoes, less than carloads.	@	.03
Large Hose, ℔ ton	@	9.00
White Wringer Rolls, ℔ lb.	@	.04¼
White Syringes, ℔ lb.	@	.05

Old Rags, Paper, &c.—A peculiarity of the Paper Stock market at the present time is the difficulty of getting offers at any price, resulting in quotations being only nominal. Such a situation has not presented itself for years, when some one could not be found to make an offer, however ridiculously low it might be. We are advised that no Rags have been imported for the past 30 days, unless previously sold, and values have so declined that dealers are afraid to buy even at the lowest price, because of probable further decline. Cholera and tariff are factors which increase the market's future uncertainty. One redeeming feature in the situation is the fact that paper mills, though not buying stock, are running full time on stock previously purchased, and if this continues it is but a question of time when they will be obliged to go upon the market as buyers. The following are the current prices quoted for Old Rags, Paper, &c., delivered in New York:

No. 1 White Rags	℔ lb	3	@ 3⅛¢
No. 2 White Rags	℔ lb	2	@ 2⅛¢
Mixed Rags	℔ lb		1¼¢
Blues and 3ds	℔ lb		1¼¢
Hard Sized White Shavings	℔ lb		2¾¢
No. 1 White Book Shavings	℔ lb	2¼	@ 2⅜¢
No. 2 White Book Shavings	℔ lb	1½	@ 1¾¢

Manilla Rope	℔ lb		2¼¢
Jute Rope	℔ lb	1¾	@ 2¢
Mixed Rope	℔ lb	¾	@ ⅞¢

Old Metals.—It might be said that there are no market prices for Old Metals, as there is comparatively no business being done in this line. The rates at which money can be obtained are so high as to make it undesirable to accumulate stock, even at the low prices now ruling. The closing down of mills and decrease of manufactured product have caused a decrease in demand for Old Metals. The following are the current quotations for Old Metals in New York:

Heavy Copper	℔ lb	9½¢
Light and Tinned Copper	℔ lb	8½¢
Heavy Brass	℔ lb	7¢
Light Brass	℔ lb	6¢
Lead	℔ lb	3½¢
Tea Lead	℔ lb	3¼¢
Zinc	℔ lb	2¾¢
No. 1 Pewter	℔ lb	14¢
No. 2 Pewter	℔ lb	7¢
Wrought Scrap Iron	℔ gross ton,	$13.00
Heavy Cast Scrap	℔ gross ton,	9.00
Stove Plate Scrap	℔ gross ton,	6.00
Burnt Iron	℔ gross ton,	4.00
Mixed Bagging	℔ lb	1 ¢
No. 2 Bagging	℔ lb	⅞¢
Hemp Twine	℔ lb	2½¢
Manila Rope	℔ lb	2¾¢
Jute Rope	℔ lb	1¾ @ 2 ¢
Mixed Rope	℔ lb	¾ @ ⅞¢

Trade Notes.

The Bailey-Farrell Mfg. Company, Pittsburgh, Pa., refer in their advertising space to a little pamphlet on the subject of lead burning, which contains much that is of interest to the trade. Its title is "How to Solder Without Solder by the Augenous Process." The pamphlet contains full instructions to the amateur in the details of the machine and the management of the gases, with valuable suggestions and directions for practice. It is illustrated, and is sent by mail at $1 a copy.

Merchant & Co. of Philadelphia refer in their advertisement this week to Camaret Roofing Tin, which they state is still carried in stock by them in Philadelphia, New York, Chicago and New Orleans. Reference is made to the quality of this brand of Plate and to the fact that all orders with which the company may be intrusted will be promptly filled.

The Specialty Wood Working Company of Warren, Ohio, direct the attention of the trade this week to a line of polished and enameled Handles, Knobs, &c., which they are prepared to furnish. The goods are made in a variety of sizes adapted to meet different requirements, and are carefully illustrated in a catalogue which the company have issued. A copy of this publication will, we understand, be sent to any address on application.

Wrought-Iron Elevator Buckets stamped in one piece and made of any desired strength give an idea of the character of the work that can be turned out by W. J. Clark & Co., of Salem, Ohio. The stamping of special articles from Plate-Metal or Wrought-Iron is made a specialty by them and frequently their customers find an order placed with them saves considerable labor and some money.

The Salem Lock Company, Salem, Ohio, are steadily increasing their output of special Door Locks and yet the favor shown the goods by the dealers keeps the demand pleasantly in advance of the supply.

F. W. Walker of the Beaver Falls Art Tile Company of Beaver Falls, Pa., recently returned home from a satisfactory visit to New York. The great variety of Tile made by the company not only find appreciation from the interior decorator, but the fire place man, the modern plumber and the stovemaker find goods that suit their trade. Some of the Tile depend for ornamentation on beautiful tints and shading alone, while others combine with this effect elegant designs or figures. One of the recent productions is a Tile about 15 inches square, with a portrait of George Washington, and, as he was the pride of his country, it is the pride of the company.

The Sun Vapor Street Light Company of Canton, Ohio, find an ample field for their system in the growth of cities beyond the extension of the gas mains and where a supplement to electric lighting is indispensable. The system requires their street Lamp and provides a graduated filling apparatus for filling the tanks, which are in duplicate sets and necessitate the route being the same every night, and when the lighter is lighting the lamp the empty tank is removed and a tank substituted. This is filled to burn to a certain fixed time, so that at that time all of the lamps are extinguished owing to the supply being exhausted. They also make a Torch which is well adapted for lighting shops and foundries, and have a Lamp in a glass globe that, if the necessary labor was used to keep them clear of dust, would give a light that should enable more profitable service from workmen.

J. M. Hadesty of Tamaqua, Pa., is again in the market with his well-known Tapping Machine. We understand that the present style of the machine is giving much satisfaction to users, and insures a continued demand for it. Mr. Hadesty is issuing new circulars descriptive of the machine and its advantages.

The Rome, N. Y., Brass & Copper Company have elected the following trustees: Samuel O. Scudder, Wiley J. P. Kingsley, Bloomfield I. Beach, Harmon G. Utley, Allen M. Wardwell, Daniel G. Dorrance, William R. Huntington, Thomas H. Stryker, Jonathan S. Haselton.

The Riehle Bros. Testing Machine Company, Philadelphia, have just received an important order from the Civil Engineering Department of the Cornell University for a 400,000 pound Vertical Screw Power Testing Machine with all the latest automatic and electric attachments, recording diagram apparatus and special tools for testing girders up to 18 feet in length, transversely; also for crushing columns 10 feet high, and for applying tensile strain to rods, bars, &c., 10 feet long, stretching them, if necessary, 25 per cent. of their length before break

This machine is without doubt the largest Screw Power Testing Machine in the country, if not in the world. The Riehle Company not long ago placed a Horizontal Hydraulic Testing Machine of the same capacity (400,000 pounds, or 200 tons) in the Boston Navy Yard. This machine weighs by means of scale levers, and is the largest hydraulic machine with levers in the United States.

THE PITTSBURGH REDUCTION COMPANY of Pittsburgh, manufacturers of pure aluminum, with works at Kensington, Pa., have just closed a contract with the Niagara Falls Power Company whereby they will receive power to run a branch plant at that place for the reduction of aluminum. The firm will erect large buildings and expect to have the works in operation early next year.

THE NEW MACHINE SHOP of the Coe Brass Mfg. Company will be 40 feet wide and 300 feet long, two stories high. The building is designed and built by the Berlin Iron Bridge Company of East Berlin, Conn., and will be covered with their patent anti-condensation corrugated iron roofing.

F. W. BLOSSOM, 124 Water street, N. Y., who deals largely in Naval Stores, Turpentine, Rosin, Tar, &c., left New York June 17, for a trip to the Pacific Coast, combining business and pleasure. After seeing the Exposition at Chicago, a week was spent in the Yellowstone Park, after which Tacoma, Portland and San Francisco were visited in turn. He will return by way of Salt Lake City, Denver and St. Louis, taking a portion of the remaining time at his disposal to see the mountain scenery in Colorado about Denver.

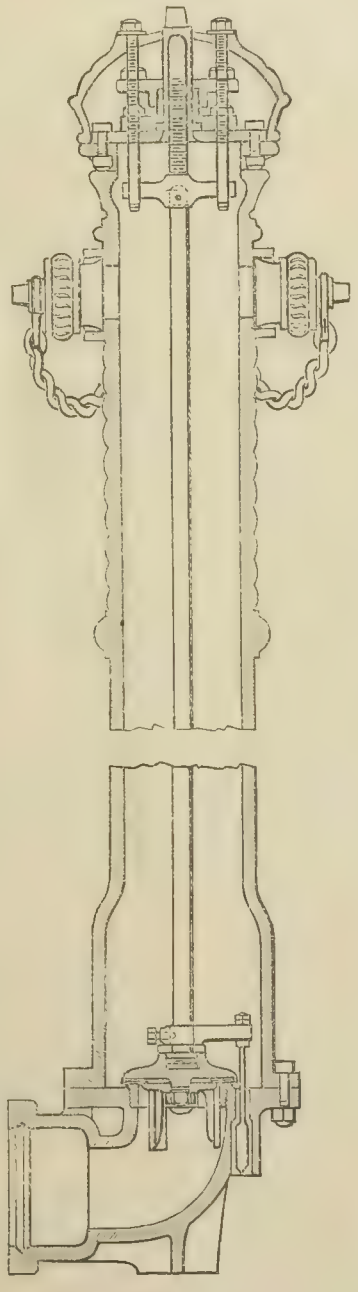
BELLEVUE PUMP COMPANY, Bellevue, Iowa, have recently made improvements in their Pumps, and refer to the satisfaction with which they are regarded, as evidenced in the largely increased demand. In their advertisement, which appears in this issue, a full description of their Galvanized Iron Tubing and Curb for Chain Pumps will be found. Further information in regard to their line is contained in the catalogue which they issue.

THE CHICAGO FOUNDRY SUPPLY COMPANY, whose Peerless Facing Mills are at Eighteenth and Rockwell streets, Chicago, have opened an office at 503 Teutonic Building, southeast corner of Washington street and Fifth avenue, in that city. They invite visiting foundrymen to call upon them at this central location, where every facility will be provided for attention to needed correspondence. The favor will doubtless be acceptable to many of those who are now making the pilgrimage to the World's Fair.

The manufacture of the Krag-Jorgensen rifle, with which first the regular army and afterward the National Guard regiments are to be equipped, has been begun at the Springfield armory. It is expected to replace the old Springfield rifle now in use in the army in about 18 months. The new weapon weighs only 8¾ pounds, and its barrel, 30 inches in length, is rifled with four grooves. The bullet of 220 grains is propelled by 37 grains of smokeless powder. It is unlubricated, covered with nickeled steel and is of such high velocity and penetration that when it strikes a bone it passes through without shattering it. It kills or disables more effectively than the old missile, but is more humane in that the chances of recovery from its cleaner wounds are far greater.

The Kennedy Fire Hydrant.

The sectional drawing here presented shows very clearly the component parts of the fire hydrant made by the Kennedy Valve Mfg. Company of 52 Cliff street, New York. The guide, stuffing box and cap are so arranged that in case of obstruction in the valve, or for necessary repairs to the main or piston drip valve, they can be removed out of the top of the hydrant, leaving the standpipe in the ground, and can be replaced in a few moments, thus obviating the necessity of digging up the standpipe. The hydrant has a positive drip, consisting of a very deep piston valve, the upper part of which has grooves to allow the water in the standpipe to flow through after the main valve has been closed. It is self-cleansing, for each time the drip is opened or closed it removes by its own action any obstruction or refuse that may have lodged in the drip. The hydrant will not freeze up where fair drainage exists, for the moment the main valve is closed all the water in the standpipe flows through the drip. The valve seats, bushing of the drip outlet and the wrench nut on top of the hydrant, are made of gun metal.



The Kennedy Fire Hydrant.

MANUFACTURING.

Machinery.

The Riehle Bros. Testing Machine Company, Philadelphia, have just received an important order from the Civil Engineering Department of the Cornell University for a 400,000 pound vertical screw power testing machine with all the latest automatic and electric attachments, recording diagram apparatus and special tools for testing girders up to 18 feet in length, transversely; also for crushing columns 10 feet high, and for applying tensile strain to rods, bars, &c., 10 feet long, stretching them, if necessary, 25 per cent. of their length before breaking This machine is without doubt the largest screw power testing machine in the country, if not in the world. The Riehle Company not long ago placed a horizontal hydraulic testing machine of the same capacity (400,000 pounds or 200 tons) in the Boston Navy Yard. This machine weighs by means of scale levers, and is the largest hydraulic machine with levers in the United States.

The Diamond Machine Company of Providence, R. I., are in position to fill orders for their regular goods promptly. The recent destruction of their property did not include their patterns. They have secured about three acres of most desirable property in Providence upon which new and modern factories will be erected, one of which will be in operation and running October 15, 1893.

Jenkins Brothers of 71 John street, New York, have made an improvement in the manufacture of a rubber compound for use on high pressure steam. For nearly two years they have been using and testing this rubber compound in the manufacture of Jenkins Disks, and the results have been more than satisfactory. They have passed the experimental stage and regard it as the greatest advancement made by them in the manufacture of their specialties.

Alfred Box & Co. of Philadelphia, are engaged on quite a number of traveling cranes, with capacities of 25 to 30 tons, and for traveling spans of 40 to 60 feet. Most of them are for use in electric light stations. The firm report business pretty brisk and have orders ahead which will keep their works running at their fullest capacity for some time.

The Gartland Foundry Company, Cleveland, Ohio, will begin work August 1. They start business with a large number of orders booked.

The Rensselaer Valve Works, Cohoes, N. Y., have just completed two large valves, weighing 10,000 pounds apiece, for a Rochester, N. Y., concern, and an order has been received from a firm in Buffalo for a 60-inch valve that will weigh 8 tons, and will be the largest ever made.

The machine, wood working and tin shops comprising the principal buildings of the North American Mill Building Company's works at Stratford, Ont., have been burned at a loss of $30,000.

The new Fitzgibbons Boiler Works, at Oswego, N. Y., have been put in operation. The first work turned out of the shop will be a 90 horse-power high-pressure boiler. The new concern will give particular attention to furnishing boilers for electric-light work and heating purposes. Already two firms manufacturing high-grade engines for electric light work have negotiated to use the Fitzgibbons boiler. The proprietor states that the outlook promises a prosperous season, with plenty of work. The old plant will be utilized by the boiler manufacturers for the present for repairs and light work connected with boiler manufacture.

The Bucyrus Steam Shovel and Dredge Works have ceased to operate at Bucyrus, Ohio, the balance of the machinery having been shipped to the new works at South Milwaukee, Wis.

Miscellaneous.

The final organization of the company who have purchased the J. S. Newmyer coal field of 2000 acres near Perryopolis, Pa., was completed at Dawson, Pa., last week and the application for a charter has been forwarded to Harrisburg. The land having originally been owned by George Washington, the company adopted as their name the Washington Coal and Coke Company.

The Berlin Iron Bridge Company of East Berlin, Conn., have received from E. D. Leavitt, consulting engineer of the Calumet & Hecla Mining Company, contract for the iron roof over their new engine house. The building will be 80 feet wide and 200 feet long.

The New York Shipbuilding & Engine Company will establish a ship yard at Whitestone, N. Y. President, E. A. Stevens (Hoboken Ferry Company); superintendent-engineer, C. D. Mosher; nav.-architect, William Gardner.

The Pittsburgh stockholders of the Westinghouse Brake Company, Limited, of London, England, recently received copies of a circular notifying them of a proposed issue of $250,000 worth of 5 per cent. bonds and which reads as follows: "You will be aware of the large increase which has taken place in the business of this company during the past three years, and of the handsome dividends which have been paid to the stockholders. The lease of the company's original works in London and Paris has recently terminated; and the company have acquired freehold land near Paris, and further freehold land at Hanover, in addition to their freehold property at York road, King's Cross, London. The lease for upward of 50 years of about an acre of ground adjacent to the company's freehold estate in York road had also been purchased. On part of the latter a foundry is in course of erection, and new and well equipped works have been built on the company's freehold in York road, as well as near Paris and at Hanover."

Current Hardware Prices.

JULY 14, 1893.

Note.—The quotations given below represent the Current Hardware Prices which prevail in the market at large. They are not given as manufacturers' prices, and manufacturers should not be held responsible for them. In cases where goods are quoted at lower figures than the manufacturers name, it is not stated that the manufacturers are selling at the prices quoted, but simply that the goods are being sold, perhaps by the manufacturers, perhaps by the jobbers at the figures named.

The character @ is used to indicate a range of price; thus discount 50&10@50&10&5 % signifies that the goods in question are sold at prices ranging from discount 50 and 10 % to discount 50 and 10 and 5 %.

News and Notes.

The receivers of the Reading road have obtained authority to issue $3,743,150 of certificates, the protests of some representatives of bond holders being overruled by the court.

A royal commission has been appointed to inquire into the causes of the present agricultural depression in England and to report to the House of Commons what means should be adopted to improve the condition of the industry.

Rumors have been given currency to the effect that a Maltese stoker off duty closed the watertight compartments of the "Camperdown" of his own accord and thus saved the ship.

The New York *World* claims to have made an exhaustive investigation into the condition of the cotton crop, having collected information from 300 centers by telegraph. The reports as summarized show: 1, That the acreage in cotton is somewhat greater than last year, and, 2, that except in a few favored localities, the condition of the crop is not promising. There has been too much rain and too much cool weather since planting time, so that the crop is backward by ten days or two weeks, and in some points of the South insects are working a good deal of harm. The reduction will possibly amount to one-fourth, as compared with last year.

Under stress of circumstances a somewhat exceptional building has been put up by W. D. F. Manice, at the corner of William and Pine streets, New York. The frontage is only 16 feet 3 inches and the depth 57 feet 5 inches, and upon this narrow strip has been built a ten-story structure 135 feet high. The owners of the adjoining properties had declined to purchase the real estate on the ground that no building could be put up on it which would justify a large purchase sum.

It is stated in the daily press that the French Government has authorized the construction of a new and powerful cruiser, to be nearly a duplicate of the United States cruiser "New York." The information has been received in United States naval circles with marked satisfaction. It is the first acknowledgment by a first-class foreign power of the superiority of United States naval construction. It will be noted, naval officers say, that the building of the new navy of the United States began in earnest as late as 1885. In less than ten years the naval constructors of the United States Navy have succeeded in developing a type of war ship which is deemed worthy of copying by France, and France possesses her own schools of naval architecture.

The contractor's trial of the new protected cruiser "Columbia" will take place on Wednesday, July 26. The "Columbia," which is still at Cramp's shipyard, is the first triple-screw vessel built by the Government. She will be docked at League Island, and while there will be examined by the Inspection Board, of which Admiral Belknap is president, her port and starboard screws will be placed in position, and she will be cleaned and painted preparatory to her preliminary trial. She is required to make 21 knots an hour.

The Maryland Steel Company are building a police patrol boat for New York.

The Bureau of American Republics is informed that the Chilian Congress has passed the act for reorganizing the currency, and that having received the sanction of the Council of State, the act has now become law. The act provides that the paper money shall be redeemed from December 31, 1899, in the new money to be coined under the act of November 26, 1892, at the equivalent value of a silver dollar of 25 grams in weight and nine-tenths fine. The paper money may, however, be redeemed from July 1, 1896, in the money to be coined under the act of November 26, 1892, or, in other words, at the rate of 24 pence per dollar. The holders of paper money, therefore, will have the option of redeeming their notes at 24 pence, or in the silver dollar of 25 grams and nine-tenths fine. The paper money will cease to be legal tender after July 1, 1896. To prepare for the new coinage provided for by the act of November 26, 1892, the silver acquired by the State under the act of March 14, 1877, the gold received in the payment of duty and storage, and up to £1,500,000 of the proceeds of the trade of Government nitrate properties, are to be maintained on deposit in the Treasury. From December 31, 1895, until July 1, 1896, the banks must maintain in gold specie or bullion a reserve fund of 20 per cent. of their authorized issue. The paper money redeemed by the State is to be burned. Half of the 50 per cent. of the duties payable in gold under the act of November 26, 1892, in the years 1894 and 1895, shall be paid in the equivalent value of paper money, and the portion of import duties and storage required to be paid in gold may be paid in good bills on London up to December 31, 1894. "Whatever diversity of opinion may exist with respect to the new act," says the *Chilian Times*, "it must be admitted that it is an improvement on the one that preceded it. In one respect, however, both acts are alike. They aim in the first line at the redemption of the paper money and the resumption of specie payments. They differ only in the means of accomplishing these ends." The *Chilian Times* adds that the Government and the country are too far committed to this policy for it to be possible for them to turn back.

Two of the ten great turbine wheels, of 5000 horse-power each, which will constitute part of the immense power plant at Niagara Falls, are now nearing completion at the I. P. Morris Works, Philadelphia. The main sluice gates, which are to admit the water from the inlet canals to each wheel, are also being manufactured in Philadelphia, at William Sellers & Co.'s, Incorporated, which firm are also building the 50 ton traveling crane to be used in the erection and management of the ten wheels. The main building, the power house of steel, which is being constructed by the Pennsylvania Steel Company, near Harrisburg, is also ready for erection.

Judge Lacombe of the United States Circuit Court, on July 1, granted injunctions to the Edison Electric Illuminating Company of New York against the Holland House and the Hotel Imperial, prohibiting them from using incandescent lamps infringing the Edison patent, under which the Edison Electric Illuminating Company are sole licenses in the city of New York. The injunction is suspended in its operation for ten days to enable the hotels in question to obtain other means of illumination. These cases were the first that have been brought against users of the Edison lamp patent as distinguished from manufacturers, and the decision is far-reaching in its effects. It is of great importance, especially in view of the recent refusal of an injunction by Judge Hallett in St. Louis against a Western manufacturer. The decision will be regarded as a rule for all users of other than Edison lamps in the States constituting the second circuit, and other suits will be immediately brought against other users similarly situated. The decision will doubtless secure to the Edison Electric Illuminating Company the incandescent lighting business in New York City, and go a long way toward securing to similar licensees the same privilege in other cities.

LABOR EXCHANGE.

Notices under this heading of reasonable length are inserted free of charge. Only those relating to employment are admitted. Write distinctly on one side of paper only, and do not use postal cards.

HELP WANTED.

At once a good STEAM and HOT WATER FITTER; state wages expected. Wm. W. Myrick, Kingston, Mass. July 15

A reliable, temperate TINSMITH who understands general jobbing, assortment work, and has some knowledge of plumbing and iron-pipe work; state wages, experience and reference. C. M. Hildreth & Son, Lebanon, N. H. July 15

By a good TINSMITH with 12 years' experience—three years in this country—at a salary of $2 a day. S. Hyman, 201 Forsyth street, New York. July 8

As FOREMAN by practical tinner of 16 years' experience at roofing, slating, cornice and furnace work; best of reference; small city in Indiana or Illinois preferred. "O. L. R.," 303½ North Thirteenth street, Terre Haute, Ind. July 8

By a TINNER and CORNICE MAKER who can cut patterns and work at hammering and stove work. Chas. J. Lindel, Tuscumbia, Ala. July 8

By a first-class PLUMBER, in city or country; best of references given. Robert Smith, 964 Third avenue, New York City. July 8

A young man, age 26, with 12 years' experience in tin, sheet-iron and cornice work and roofing, understands plumbing and gas fitting and does all kinds of general jobbing, speaks English and German, desires a steady position. H. Altman, 83 Sheriff street, New York City. July 8

By a young man, a steady situation as PLUMBER, to work under instruction; graduate of New York Trades School; has had considerable experience at trade; good reference. P. O. Box 39, Moundsville, W. Va. July 8

TINSMITH and ROOFER, and for other general jobbing. Jacob Samuals, care of Mr. Dzalka, 110 Clinton street, New York City July 8

By a STOVE IRON PATTERN FITTER; several years' experience. "J. L.," office of *The Metal Worker*, 96-102 Reade street, New York City. July 8

CORNICE and SKYLIGHT MAKER, CUTTER and DRAFTSMAN; a thorough mechanic in all branches; capable of taking charge of shop; has experience as foreman; understands handling help to best advantage and work; would like a steady position. "C. D. F.," office of *The Metal Worker*, 96-102 Reade street, New York City. July 8

As PLUMBER by a sober and industrious young man; city or country. Henry J. Schlag, 420 East Fifty-ninth street, New York City. July 8

Position in good cornice shop to assist in cutting and work under instruction; state wages to a steady man. Chapman & Chapman, Hutchinson, Kas. July 8

By a TIN and SHEET-IRON WORKER with ten years' experience; city or country; New York preferred; sober and industrious. "A. G.," care of B. Abel, 189 Christie street, New York. July 8

SHEET METAL PATTERN CUTTER desires position in a first-class cornice shop; thoroughly competent to take entire charge, New York or vicinity preferred. "Pattern Cutter," office of *The Metal Worker*, 96-102 Reade street, New York City. July 8

BRASS FINISHER, soft and hard solderer; city or country. Louis Fried, 124 Lewis street, New York. July 8

PATENTS

U. S. and Foreign Secured.

Trade Marks and Copy Rights. **Twenty Years' Experience.** Send model or sketch and brief description of your invention for **Free** report as to patentability. Expert searches and opinions as to Scope, Validity and Infringement. Patent Causes Prosecuted and Defended. Practice in U. S. Supreme, Circuit and Circuit Appeals Courts, and U. S. Patent Office.

BENZINE OR WATER

Paste Stove Polish at 4 to 6 Cts. per Pound.

Guaranteed the best. None better.

Send for circulars.

YATES & CO., Rockford, Ill.

Special Notices.

FOR SALE.
BARGAIN.

A well-established stove, heater and range business. Been established 30 years. Good reason for selling.

E. J. MAHOOD,
1642 Market St., Philadelphia.

FOR SALE.

A large hardware, stove and sporting goods store; also a full set of tools for the manufacture of tinware; located in the heart of Freeland; a good established business; a rare chance. Reason for selling is to retire. Write for full particulars to

THOS. BIRKBECK,
Freeland, Luzerne Co., Pa.

FOR SALE AT A BARGAIN.

An old and established tin and stove store in a fast growing town. A good chance for a man with some knowledge of plumbing and steam fitting. Good reason for selling. For full particulars address
E. P. KEEVER, Hummelstown, Dauphin Co., Pa.

WANTED.

A second-hand Squaring Shear, 30 inch; in good order.

HOWARD FURNACE CO.,
210 Water St., New York City.

FOR SALE TO CLOSE AN ESTATE.

Fine Hardware, Stove, Tinware and Plumbing Business.

Doing a first-class retail and jobbing business in a growing Western town. Stock will inventory about $35,000. A rare chance, as present owners have been liberal advertisers. Only those who mean business need apply. Address "B.," office of *The Metal Worker*, 59 Dearborn St., Chicago.

TRAVELING SALESMEN.

A large commission to handle the Diamond Extension Stove Back. Aluminum model furnished. Sells nicely as a side line. Any part of the United States. One dozen weighs 100 pounds. Apply to

THE ADAMS COMPANY,
Dubuque, Iowa.

A RARE OPPORTUNITY.

A Plumbing, Gas Fitting and Tin business for sale. Well established and good paying business in growing town on south side of Long Island; store property for sale with business; good reasons for selling. Address "RARE OPPORTUNITY," office of *The Metal Worker*, 96-102 Reade St., New York.

!!! FOR SALE !!!

BAKER BLOWERS, Nos. 1, 4½, 5, 6 and 7.
ROOT BLOWERS, Nos. 1, 2, 3, 4, 5, 6 and 7.
Sturtevant Blowers, Nos. 4, 5, 6, &c.
1 Corliss Band Wheel, 12 ft. x 24 in., in halves.
A variety of Machinery, such as Boilers, Engines, Pumps, Crushers, &c., very cheap.
Do you want to buy or sell Machinery? If so, write

C. R. BIGELOW, Machinery Expert,
45 Dey St., New York City.

FOR SALE.

A well established Plumbing business; can give good reason for wanting to sell. Address
"BOX 578," Bristol, Conn.

FOR SALE.

3 sizes of first-class Wood Cooks and 4 sizes of second-class Wood Cooks; 2 sizes of first-class Coal and Wood Cooks, 3 sizes of second-class Coal and Wood Cooks; all follow boarded and with flasks. For cuts and prices address

HENRY SMITH,
office of *The Metal Worker*, 5th and Main Sts., Cincinnati, Ohio.

ESTABLISHED 1853.

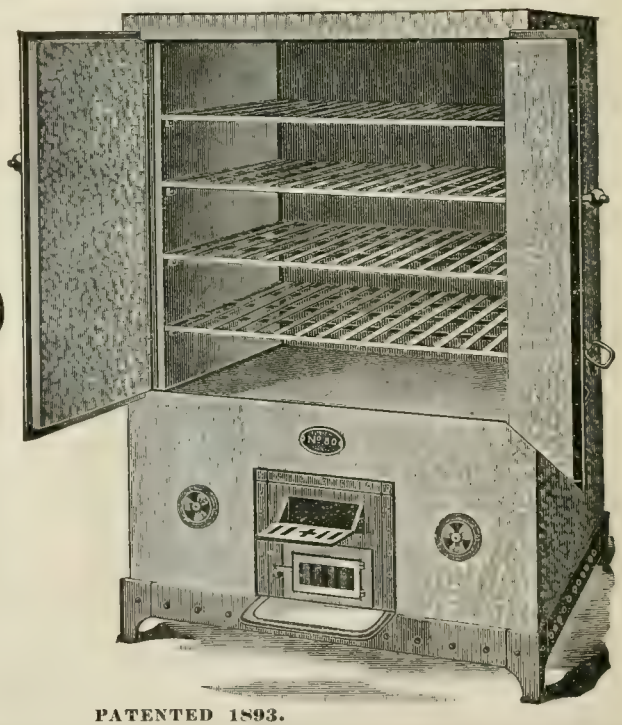
The trade cannot fail to be benefited by corresponding with us on Hot Water Heating.

Baking by Circulation.

The A. B. Kingsland & Co.'s Improved Portable Baking Oven is the only Oven in the market that bakes by PERFECT circulation of hot air.

ADAPTED FOR COAL, WOOD OR GASOLENE FUEL



PATENTED 1893.

By *our method* of circulation, an even temperature is secured and maintained throughout all parts of the Oven, thus insuring an even bake to all articles.

Guaranteed to be more economical, quicker in circulation and more durable than any other Oven in the market. Write for illustrated circulars.

A. B. KINGSLAND & CO., - BURLINGTON, VT.

SPECIAL NOTICE TO THE TRADE.

Hold your order for the heavy beveled French Plate Glass in Oven Door. All parts of oven exposed to view when door is closed. Our salesman will call on you with sample in June or July.

BRITISH AGENCY: The Ironmonger, 42 Cannon street, London, England.

Col. R. T. Auchmuty.

The news of Colonel Auchmuty's death, given in another column, will come as a shock to many who knew and loved the man. It is, however, some consolation to feel that he passed away leaving the great work of his latter life complete. He had the satisfaction of seeing the enterprise which he founded single-handed, and engineered to a successful issue, flourishing and standing on the firm basis now held by the New York Trade School. The importance of Colonel Auchmuty's work and the untiring zeal and labor expended by him in its accomplishment cannot well be overestimated. Possessed with a passionate enthusiasm for promoting the welfare of young men and a clear idea of the best means for insuring their welfare—namely, to help them to help themselves, the Colonel set himself to work to carry out his conceptions with an earnest purpose and determination which brought success with it. The influence of his personality, too, was far-reaching. Hundreds of students who have passed through his school are now witnesses in every quarter of this country and in Canada to the wisdom and efficiency of Colonel Auchmuty's methods of training, and many feel the beneficial effects of their personal contact with this best type of Christian gentleman at a time of their life when good influences were most needed. In the New York Trade School a lasting memorial will stand, always linked with his name, and in it, "he being dead, yet speaketh."

A Novel Profession.

The host of labor disputes which have marked the past few years in England, and the great loss and inconvenience attendant upon strikes, have caused the evolution of a new profession in that country. There has arisen a class of leaders of men, termed "strike defeaters," whose business is that of breaking down strikes, not by physical or military force, but by the more peaceful method of doing the work of the strikers until they come to terms. One of the most prominent of these individuals, whose name is Graeme Hunter, is described as a powerful, energetic man in mind and body, who lives with his men, but rules them with strict discipline. His methods are in some respects peculiar, and appear slightly arbitrary to an American mind. As described by English journals, Mr. Hunter's system is as follows: He has the reputation of never interfering in a strike until all means of settling it have been exhausted and he believes the strikers to be in the wrong. Then he simply puts his men to work and keeps them at it. He tells his hands how much he gets to do the job, and the way he makes his own remuneration is by simply dividing the whole amount among them according to their labor, less 1 penny out of every 5 shillings they earn, over and above the expenses incurred. He has under his control some 3200 men, whose average wages are about $6 a week, besides board and lodging. They are all obliged to live together near to where they may be working, and Mr. Hunter insists on every married man sending home at least £1 a week to his wife, paying them this amount in postal orders, collectable at the home of the wife. Fines are exacted for the absence from work, &c., and no recognition of union rules is had. It is said that eight of his gangs were recently employed at eight ports, including Liverpool, Glasgow, Greenock, Dublin and Bristol, by which it would seem that these men are all-round laborers and not skilled workers.

The World's Fair.

Every returning visitor to the World's Fair is becoming an active missionary in his home in behalf of that grand undertaking. The influence of this labor of love can hardly be overrated. The enthusiasm of a friend or an acquaintance is catching. It is far more convincing than columns of cold type. Doubts are dispelled, objections are quickly overcome and the conviction is reached that ways and means must be carefully studied to settle the question whether a visit is feasible. Questioning concerning some special interests put to the returning traveler often fails to bring satisfactory information and stregthens the belief in the necessity for personal inspection. We may confess that we have been taken by surprise by the unanimity of the enthusiasm aroused with persons differing widely in temperament and in tastes. A good deal of downright wicked work on the part of some of the daily newspapers, notably in the East, is being undone now by those who come home to relate their experience. Whatever may have been the shortcomings during the early days following the opening of the fair, they are now completely removed. The exhibition is a harmonious whole, beautiful beyond anything yet created by man in this country, and in grandeur surpassing any similar attempts at home or abroad. Architecturally and artistically the structures of the White City will prove a revelation and are likely to cause a reaction to a purer and chaster taste in our public buildings and private dwellings. We look forward to as decisive an influence upon the taste of the people as was that created by the Centennial Exhibition. Gaudy frills will not sell as well as they have done, and it will be a wise course on the part of manufacturers of goods ornamented in any way to closely watch developments in this direction.

Increasing Attendance.

Until now the visitors to the fair appear to have been drawn from a moderate distance of Chicago, while the majority of those who have traveled further than 200 miles are well-to-do people. From a study of those in attendance and talks with many people we are convinced that the rush has really not begun yet. That it is coming we have little doubt. Lower rates of fare, the steadily growing interest, and the fact that the vacation season is at hand, will all contribute to swelling the attendance. It is beginning to be understood, too, by the financially timid, that the tales of extortion rest on a very slim foundation. Experts who expect to be overwhelmed with novelties in their own special branch will be doomed to disappointment. Our technical press is too vigilant and too enterprising to permit of many startling revelations. But in these days of specializing, the manufacturer, the business man and the engineer can spend many hours profitably in an inspection of exhibits illustrating recent progress in cognate industries. But after all the main object and the principal achievement, from an educational point of view, of this like every exhibition, is the enlightenment which it brings to the masses, whose range of vision it expands, whose mental activity it stimulates and whose tastes it elevates. The World's Fair, which is Chicago's glory, is becoming the pride of every American, and is bound to have a wonderfully invigorating effect upon the people.

Will Not Give Notes.

A correspondent states a rather novel experience, which, he says, is proving quite a serious matter in some lines of trade. Large manufacturing establishments owe him for supplies. The accounts are overdue, yet he can neither collect the money nor obtain notes, which he might be able to have discounted. He is simply told that he cannot be paid just now and he will have to wait. They never have given any paper out and do not propose to begin now. This is not a solitary case, but has plenty of company. It is a suspension of payments brought about by the scarcity of money and the inability to obtain assistance from banks. These large concerns know they are perfectly solvent, but, as they do not have ready money, they cannot pay their bills and they will not put out evidences of indebtedness which must be promptly met when due. It is a bad condition of affairs, but what can be done to make it better?

Taking Foolish Risks.

The cold storage warehouse at the World's Fair was burned last week, and nearly two score lives were lost merely because a metal thimble had not been put on the smoke stack to prevent it from coming in direct contact with wood. Here was $250,000 worth of property constantly in jeopardy because none of the managers of the warehouse took enough interest in the protection of the property from fire to look after the due completion of the smoke stack. The architect says it was not his fault, because he merely made the plans. The owners say they thought it would do as it was. And yet insurance companies had refused to write policies on the building, because their agents condemned it as too great a risk. One of them said: "It is not even a risk, because it is sure to burn down some time." Under such circumstances it seems almost incredible that owners would themselves take risks refused by insurance companies. The owners were willing to risk all they were worth that a spark would not some time set fire to the surrounding wood work. And yet are not such risks being taken continually by manufacturers and others? They may not be quite so glaring as this seems to have been. We hope that not another case can be found in which sparks are permitted to play directly against wood work. But there are other risks, dangerous to persons and property, which manufacturers are too apt to take. After a serious mishap, when the cause is laid bare, every one will wonder how it could have been overlooked. Yet he himself may be overlooking some very serious risk he is taking at that time. An excess of caution is better than foolish confidence, which is often nothing more than insane recklessness.

Where Is the Point?

BEN BURNT.

The lodge meeting was in session, but as our cigars were not smoked up we were puffing in the anteroom. Bill said things was pretty "middlin'" tough, for bid where you would some "skin" would cut you out. Tom agreed with him, and the whole gang was a "sympathizin'" as though their clothes were sackcloth, and to "mourn with them that mourn" was the fluid extract of earthly joy, when Ephraim Smooth spoke.

"Boys," said he, "let me put a golden stripe on that streak of blue you have been showing, by giving you a pointer. Once there was a fellow who was rich, gosh! but he had the stuff. Well, he had two big jobs to do, and there were lots of fellows who could do them, but only two were asked to bid. They both wanted both jobs, but didn't have sense enough to know that if they got both they would be stuck to get the work done in time, and, consequently, it wasn't likely that either of them would get both. They knew that a certain sum of money had been calculated as about the proper size, but they both bid, and one of them got it at 33⅓ per cent. below the estimated cost. The other fellow howled that it couldn't be done without losing 10 per cent. on what it would cost; and so it went. Well, when the other job was ready, they both bid again, and this time the other fellow got the work at 20 per cent. below the figure the 'stuffed purse' had set. Now, the first fellow said nothing and sawed wood. The other fellow went along with his work according to the patterns sent, and one day he called in his men and told them he was behind time with the job and was about to lose 10 per cent. on the whole job, which was enough to make any one of them rich."

Right there Eph. stopped talkin', and some of the fellows said they didn't see no point. Eph. says:

"You don't, eh! Well, let me illustrate by a further figure of speech. This same Crœsus wanted a lot of other stuff, and three wise men in that land were told about it, but they didn't rush around before day to see what it was. They arrived, however, in due season, and found out what was wanted, and each figured the cost, added on a fair live-well-and-lay-something-by profit, and met the others. John said, 'Boys, I am busy with orders for three months, and this work is wanted now, but I can look sweet and promise nice if necessary.'

"Samuel said: 'I shall be busy longer than that with part of my hands, but not all, though they can help the others out, so I shall be all right.'

"Elias said: 'I am quite busy right now finishing up some orders, but in a month I will be ready for it all.' John and Samuel said 'Git thar, Eli,' and they agreed that Elias should have the job, but he was to pay them a small commission and get what he needed at the start from them at regular rates.

"They knew what 'Gold Grower' had calculated the cost to be, which was $5. So John was to bid $5.30, Sam was to bid $5.15 and Elias just even $5, and all of their bids were sealed and sent in. In a few days 'Amasa Cash' sent for Samuel and said: 'Samuel, I know your reputation and like your goods, but will have to give this work to a lower bidder, unless you are willing to do it at his price.' Samuel looked grave and asked how much too high he was, and he was told just 50 cents. So Samuel said he would consider the matter, but Amasa Cash told him that he had the letter written, to be mailed that day and he could not wait longer than afternoon. Samuel returned in the afternoon, saying that he was very much obliged for the chance to figure again, but he could not take the work any lower, so Elias got the job."

Eph. then asked 'em again, "Do you see the point?" Well, some of them seemed dazed, so he said: "If them first fellows had acted like brothers, as they have good Scripture for doing and had taken what the rich fellow was willing to pay, which you can bet was low enough, they would feel less like you fellows. If you fellows profit by what I have suggested rather than what I have said, there ought to be enough in that profit for a small commission for me." Well the lodge adjourned about then and some of them fellers couldn't sleep that night for thinking.

Effects of Temperature on Canned Foods.

Concerning the keeping qualities of canned foods when exposed to extremes of heat and cold Adjutant-General Williams, in a recent army circular, publishes the following information:

"Apples, peaches, pears, rhubarb, green peas, green corn, onions, potatoes and tomatoes were all subject (at Lady Franklin Bay) to extreme temperatures (over 60 degrees below zero), and were solid for months at a time. The second summer they thawed, the following winter froze solid again. All the articles named presented the same appearance as though freshly canned, and their flavor was as good when the last can was eaten as in the first month. It should be understood that these were first-class canned goods and from dealers of standing and reliability. Cranberry sauce, preserved damsons, preserved peaches, and fruit butters suffered certain changes from candying, &c., which detracted somewhat from their flavor, though not materially so. Dealers in such preserves predicted that such conditions and changes would occur. I had also canned turnips, squash, beets and carrots, as well as pineapples, cherries, grapes, clams, shrimps, and crabs, which, although not subjected to such extreme temperatures as the foregoing, yet froze and thawed repeatedly without injury. No can of any kind except a few, say half a dozen of fruit butters, was ever burst by action of cold or heat."

Dr. Simson Pratt of the British army says:

"Taking my experience in India and the late Nile expedition, in which the test of tinned provisions was exceptionally severe from continued exposure to the powerful direct rays of the sun, I have found that tinned provisions, meat and vegetables put up separately, or combined in the form of soups, are practically undamageable by any climatic heat.

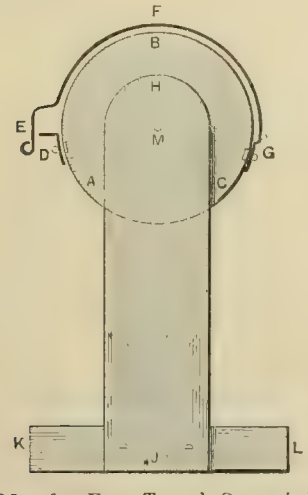
"The only class of provisions that, in my experience, suffers from great heat is that of uncooked articles, such as butter, cheese and some forms of potted meats."

The Trunk Line Association has reduced the fare from New York to Chicago to the price of one limited fare for the round trip. The ticket is good for ten days. Two excursions will be run on Mondays, Tuesdays, Wednesdays and Saturdays of each week, to be alternated by the several lines. On the Pennsylvania and Central the fare will be about $20 for the round trip. On the West Shore and Erie it will be about $18, and on the Ontario & Western, $17.

THE LETTER BOX.

Holder for Eave Trough.

From J. T. S., *Jackson, Ga.*—In answer to the Ohio correspondent who wishes a trough for soldering eave trough in, if he will make a holder as described below there will be no trough required. Make a sheet-iron cylinder, A B C, the diameter of gutter and 4 feet long, or longer if desired. Form a strip of iron the length of cylinder and rivet to same, as shown at D. This forms a straight edge for the bead on trough to rest against. Then form two or more wire springs, as shown by E F G, for holding the trough in position while soldering. These springs are to be hinged to the cylinder as at G, and bent so as to go over the bead and lock over D, as shown at E. The springs are hinged at G, so they can be turned back to release the trough after it has been



Holder for Eave Trough Suggested by "J. T. S" Jackson, Ga.

soldered. Then cut two disks from 1-inch board to fit in the ends of cylinder and which can be secured in place by nailing. In the center of each disk, as at M, drive a wire for the cylider to revolve on. A 6-inch board, K L, for stand, and two 8-inch uprights, similar to H J, complete the machine.

Flat Seams on Large Tin Roofs.

From E. F. B., *Greenville, Pa.*—I would like to have some practical tin roofer tell me through the columns of *The Metal Worker* why large tin roofs with flat seams are, as a general rule, laid with the long seams running crosswise of the roof. Would it not be better to lay the roof with the long seams lengthwise of the building? It seems to me it would give a better opportunity for soaking the solder in the seams if this plan were followed, and the water would run off better.

Protection for Planished Iron.

From R. R., *Coldwater, Mich.*—I would like to be informed through the columns of *The Metal Worker* of some composition for preventing planished iron from rusting.

Answer.—Vaselene is said to be a rust preventive when applied to the surface of iron. If the iron is covered with a thin coating of boiled linseed oil the oil will soon dry and form a coating impervious to moisture, and can be removed with turpentine when required. A cheap varnish can be made by adding 6 ounces of rosin to 1 gallon of gasoline and scraping in a small quantity of paraffine. The following recipe has been recommended for the purpose :

Pulverized alum	4 ounces
Pulverized borax	4 ounces
Pulverized stove polish	4 ounces
Pulverized rosin	6 ounces
Lampblack	2 ounces
Gasoline	1 gallon

In case the above is to be used only for a varnish, the stove polish can be omitted. One ounce of beeswax to 1 pint of gasoline is said to make a good protection for planished iron. We should be pleased to have our readers give any further information on the subject.

Soldering Galvanized-Iron Trough.

From C. B. G., *Bridgeton, N. J.*—In answer to "H. B.," Lebanon, Mo., who inquires in *The Metal Worker* of June 17 regarding a proper way of soldering the perpendicular seams in an old ogee hanging gutter, would say that I have repaired broken seams in deep gutters where it would be difficult to solder with a copper by the following method: The seams are to be well tinned, then take a half tube of galvanized iron, about ⅜ inch in diameter and as long as the gutter is deep. Place this half tube over the seam, holding it close against the trough by means of a cloth of sufficient size. Then take a hot soldering copper and melt the solder into the tube, which will hold the solder against the trough until it cools. The half tube can be left in position or taken off and used for another seam, as may be desired.

Trouble With a Well Cooler.

From E. A. W., *Chester, Vt.*—In reply to the inquiry of "P. R. F.," which appeared in a recent issus of the paper, I would say that if the correspondent will extend his inlet pipe across the boiler to within 2 inches of the opposite end, and do the same thing with the outlet pipe, so that the openings of the two are as far apart as possible, satisfactory results will be obtained.

From R. M. B., *Spencer, Mass.*—I would like to offer a suggestion for remedying the fault in the water cooler referred to on page 33 of *The Metal Worker* of July 8. My suggestion is that if the inlet pipe came in at the bottom and the outlet pipe went out at the top the results would be better for two reasons. In the first place, there must, necessarily, be an air space above the line of the two pipes as the tank now stands, which would lessen the volume of water which the boiler would contain. Thus the 18-gallon boiler would be reduced to, perhaps, 10 gallons. In the second place, where the inlet and outlet pipes are directly opposite, a flow is induced between them, and the water will not circulate throughout the whole boiler.

Barker's Chimney Top.

From Frank Hagerman, *Hanover, Kansas.*—Will some reader of *The Metal Worker* please inform me where I can obtain information about Barker's Chimney Top?

Retinning a Bathtub.

From E. W., *Orange, N. J.*—Please inform me through the columns of *The Metal Worker* how to retin a bathtub.

Answer.—It is supposed that the bathtub in question is lined with tinned copper, and the tin coating has been worn away by use. Under such circumstances it would be necessary to remove the lining before it could be retinned. Such tin as adheres to the copper can be removed by washing with commercial muriatic (hydrochloric) acid, using for the purpose a swab of tow twisted about a stick, to prevent the acid from coming in contact with the hands. The surface is then to be scoured with sharp sand, salt and water, when it can be rinsed with water to see that it is clean. Another method for removing the tin is to take some clay, pound it up fine, and then sprinkle on salt and powdered sal-ammoniac. The above compound is then to be well mixed and moistened with water so as to form a thin paste. The mixture is then spread over the partly-tinned surface of the copper, and then held over a charcoal fire until the copper becomes red hot. If a sufficient amount of salt and sal-ammoniac has been used, the clay will curl up, taking the tin with it. If desired, the strength of the mixture can be first tried on a small piece of tinned copper, if not strong enough to remove the tin, add more salt and sal-ammoniac. The copper is then to be scoured with sand, salt and water. Having cleaned the copper by either of the above methods, it is ready for tinning. A bunch of tow, soldering acid, tin and powdered sal-ammoniac are then to be procured. Brush the surface of the copper over with soldering acid and drop on some pieces of tin. Then place the sheet of copper over a charcoal fire, gas or kerosene stove, until the tin begins to melt. Then dip the bunch of tow into the powdered sal-ammoniac and spread the tin over the surface of the copper. This operation is to be continued until the surface of the copper has been covered with tin. Care is to be taken in the meanwhile that the copper is not overheated, which will cause the tin to look yellow. While the various operations may be performed with skill, it will be difficult to produce results as satisfactory as would be secured by putting in a new bathtub.

PLUMBING and GAS FITTING.

Experiments with Water Traps.

In the *Sanitary Journal* of Glasgow, Scotland, appears an able and interesting paper by Dr. Neil Carmichael, examiner in public health to the faculty of physicians and surgeons of Glasgow, entitled "Plumbing and House Drainage in Relation to Public Health." In this paper Dr. Carmichael gives the account reprinted herewith of some experiments conducted by him to determine the reliability of water traps for preventing the passage of sewer gases and germs from the soil pipe into the house.

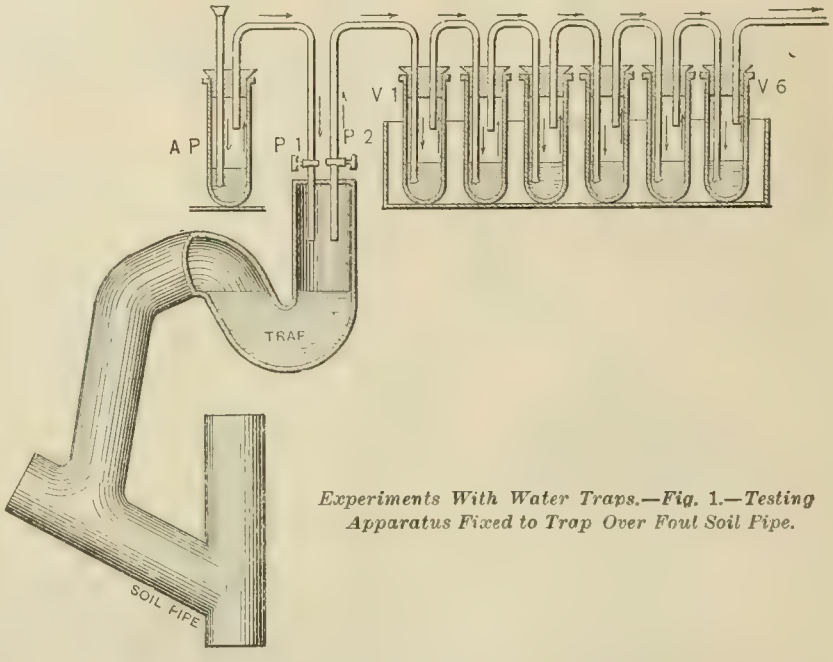
Premising that one of the main objects of good plumbing is to secure the rigid exclusion from our houses of the processes of putrefaction and the products of putrefaction, the author asks: How do the gases and germs contained in soil pipes and drains gain entrance to our houses? Not through solid lead or iron pipes. Gases do pass through these metals, but in quantities so infinitesimal as to be absolutely harmless. Do the gases pass through the seal of the water trap? The late Dr. Andrew Fergus of Glasgow, performed some very interesting experiments with glass tubes formed to represent traps. He found that carbonic acid, sulphureted hydrogen, and ammonia, placed in one limb of the tube, passed through the water in the bend of the tube, and could be detected in the air above the trap on the free side in from 15 minutes to three or four hours. When the tubes were ventilated, the time of transmission was slightly increased. These experiments determined the fact that gases could be dissolved by the water in the trap, and be passed out on the other side. In these experiments, the gases employed were presented to the surface of the water in a very concentrated condition. To what extent do the gases and germs of an ordinary soil pipe pass through the water seal of a sound trap?

GASES DO NOT PASS SOUND TRAP.

To determine this point, says Dr. Carmichael, I performed a series of experiments. The experiments were performed with an ordinary lead trap connected to a soil-pipe. The soil pipe was old; its internal surface was foul; into it there discharged three water closets; it was ventilated above by a 2-inch pipe, and it discharged untrapped into the drain. The lead pipe on the house side of this trap was closed by soldering on to it a plate of zinc, through which passed two small lead pipes into the air cavity above the trap. Air of the room, purified from the gases to be tested for, was, by passing it through an absorbing solution, A P, Fig. 1, drawn continuously by an aspirator through this cavity, and then made to bubble through testing solutions, V1-V6. This was continued for several days at a time, and the experiments were frequently repeated.

It was found that in 24 hours about 7 grains of carbonic acid passed through the trap, when the ventilator on the roof was open, and that when this was closed about 32 grains passed through. Ammonia passed through from the ventilated pipe to the amount of about the two-hundredth of a grain, and, when the ventilator was closed, to the extent of about the hundredth of a grain. The amount of sulphureted hydrogen passing through the trap when ventilated was about the hundredth of a grain, when unventilated it was about one-eightieth of a grain, in 24 hours. Putrid organic vapors, if they passed through, were included in the ammonia, and were never found to come through the trap in such an amount as to be detectable by smell. As the largest amount of ammonia found to pass through was about the one-hundredth of a grain, the putrid organic vapor included in this amount must have been very small indeed.

The quantities of injurious gases and vapors, therefore, which pass through the trap from the soil pipe—even a foul unventilated one, directly connected with the drain—are exceedingly minute, and from a health point of view must be considered absolutely harmless. The foul gases of the soil pipe and drain therefore do not gain entrance to our houses through a sound water trap.



Experiments With Water Traps.—Fig. 1.—Testing Apparatus Fixed to Trap Over Foul Soil Pipe.

PASSAGE OF GERMS FROM SOIL PIPE.

Do the germs of putrefaction or other germs contained in the soil pipe pass through the trap into the house? To determine this point I performed a large number of experiments, a few of which may be briefly described. The lead trap, already mentioned, connected with the soil pipe, and closed on the house side by a plate of zinc

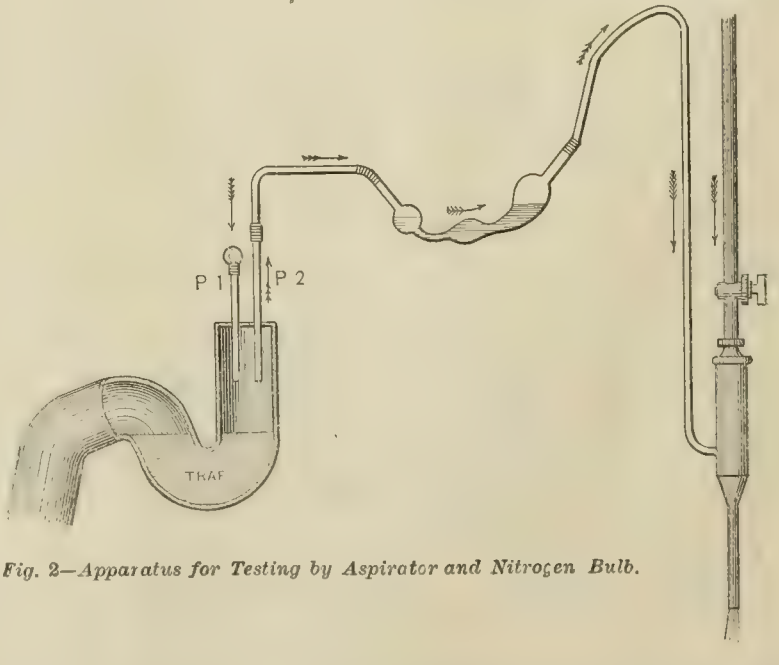


Fig. 2—Apparatus for Testing by Aspirator and Nitrogen Bulb.

having two pipes passing through it into the cavity above the water, was connected, as shown in Fig. 2, by one of the pipes—P 2—with a nitrogen bulb, that is, a glass tube—with alternate contractions and expansions. In this bulb was placed a cultivating solution, that is, an organic solution in which microbes can readily grow when they have been introduced. The bulb was connected with an aspirator, which, when the water was turned on, drew the air through the bulb. The other tube, P 1, leading into the cavity above the traps was at first left open. A pot containing melted paraffin wax was placed under the lead trap, so as to immerse the trap in the wax. This was heated until the water in the trap boiled freely and steam was blowing out freely through the open pipe, P 1. The liquid in the bulb also was boiled. This boiling killed all germs which were contained in the trap and in the bulb—it sterilized the apparatus. A large pad of sterilized cotton wool was placed over the mouth of the pipe, P 1, from which the steam was escaping, and the heat was then removed.

When the trap had cooled the aspirator was started in action by turning

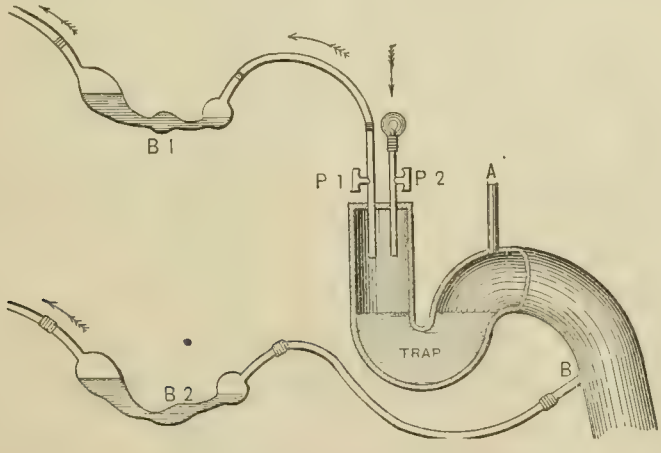

Fig. 3.—Tests of Air Direct from Soil Pipe.

on the water. The air of the room, filtered of its germs by passing through the cotton wool, entered the cavity above the trap, mixed there with the gases and air contained in it, and was then drawn in a series of bubbles through the liquid in the bulb. If any germs pass through the water trap from the soil pipe they must have been carried into the bulb.

The aspiration was usually continued for from 24 to 36 hours. The bulb was hermetically sealed before removal and was placed in a room heated to cultivating temperature. The liquids in those bulbs, though kept for several months in some instances and at cultivation temperature, remained perfectly clear, and exhibited, on careful microscopical examination, no trace of life; that is to say, no germs had passed through the water trap. For comparison, the air of the soil pipe was made to bubble directly through a similar bulb, B 2, Fig. 3. The liquid in this case, became hazy from particles, and developed fungi and bacteria in abundance.

GERMS FROM PUTRID LIQUID IN TRAP.

It might be objected, to the experiment with the trap just described, that the water contained in this trap was sterilized, and that the water ordinarily found in a trap is more or less putrid. Would putrid liquid give off its germs to the air above it? To determine this I poured into the trap already mentioned, through a pipe, A, Fig. 3, on the soil-pipe side of it, about a pint of urine. A portion of this remained in the trap, mixed with the water previously contained. This speedily putrefied. Aspiration of the air above this trap through the cultivating liquid in the bulb was continued for a week. The liquid in the bulb did not putrefy nor develop life—that is, the putrid water in the trap did not give off its germs to the air above it.

These results are in entire consonance with the results obtained by many other modes of experiment. Sound water traps, properly placed and having a proper seal or water lock, are therefore, for the exclusion from houses of injurious substances contained in the soil pipe, perfectly trustworthy. They exclude the soil-pipe atmosphere to such an extent that what escapes through the water is so little in amount and so purified by filtration as to be perfectly harmless, and they exclude entirely all germs and particles, including, without doubt, the specific germs or *contagia* of disease.

DESTRUCTION OF SEAL BY SYPHONAGE.

Yet there are conditions under which traps may fail to protect. They may be so placed that the water seal is destroyed. The water in the trap may be syphoned or aspirated out till the seal is destroyed. Expansion of the atmosphere in an unventilated soil pipe may cause the soil-pipe air to bubble through the trap. To determine the condition of the air which bubbled through the trap the following experiment was performed: With the apparatus arranged as before, except that the pipe, P 2, Fig. 3, through which the air had previously entered was now closed, the aspiration was started, and air not being obtained through the small pipe, the soil-pipe air bubbled through the trap. The liquid in the bulb in this case became hazy and developed bacteria and mold. Soil-pipe air bubbling through the trap carries with it the germs, and if this soil-pipe air contained the germs of specific diseases, these would doubtless be conveyed to the atmosphere of the house.

These experiments establish the reliability of the water trap, if sound and well placed, and emphasize the importance of ventilation of the soil pipe, and of so arranging the pipes that pressure and syphoning may be avoided.

THE MOSELY FOLDING BATH TUB COMPANY, 181 South Canal street, Chicago, have the past week shipped 50 of their outfits to the Union Nut Company, one of the largest export houses in New York, as a result of their critical and expert examination into the merits of these goods, which are fast growing in public favor. The Union Nut Company propose to push the sale of the Mosely outfits with their extended South American connections, and predict large developments. The Mosely Folding Bath Tub Company have made application for patents in many foreign countries, some of which have been granted, and they believe that all applied for will in due time be obtained. The company have every reason to be pleased with the condition of business, considering the unsatisfactory state of the country generally, their trade being good, with orders waiting to be filled.

Colonel Richard T Auchmuty.

Many readers of *The Metal Worker* will learn with unfeigned sorrow of the unexpected death of Colonel Richard T. Auchmuty, the founder of the New York Trade School, which took place at his summer home in Lenox, Mass., on Tuesday, July 18. The immediate cause of death was œdema, or dropsy of the lungs. The Colonel sustained a severe injury to one of his legs during the war, from which he suffered more or less for many years. Last March the limb was amputated, and Col. Auchmuty was believed to be regaining strength after the operation. He was able to be moved about in his chair until last week, when a collapse set in and he sank rapidly.

Richard Tylden Auchmuty was born in New York City in 1831, and was a member of an old New York family that emigrated to this country from Scotland early in the last century. His great-grandfather, the Rev. Dr. Samuel Auchmuty, became rector of Trinity Church in 1763. After graduating from college, Colonel Auchmuty studied architecture with James Renwick, whose partner he subsequently became. He was appointed Assistant Adjutant-General of Volunteers at the outbreak of the war, and served during the years 1862 and 1863 in the Army of the Potomac. Ill-health compelled him to apply for relief from active duty in the field, and he received orders in 1864 to report for duty in Washington. He remained in the War Department until the close of the war, with the added rank of Major. While still quite young Colonel Auchmuty married Miss Ellen Schermerhorn of the well-known New York family. Miss Schermerhorn was the daughter of the late P. A. Schermerhorn, and she survives her husband. The fortune brought him by his wife, added to his own, enabled him to retire from active business life and devote his time and energies to philanthropic pursuits. Colonel and Mrs. Auchmuty had no children, and spent large sums in unostentatious charity.

Colonel Auchmuty will be best remembered as the founder and promoter of the New York Trade School, to the interests of which he devoted the best energies of his life for the past twelve years. This institution was established by him in 1881, after considerable study of the subject of manual training as conducted in Europe. About $50,000 were originally laid out in land and buildings. Although meeting with many discouragements and obstacles at first, the Colonel labored indomitably with tongue, pen and purse for years until success came, and his project and the system of manual training devised by him blossomed into the widely known and successful establishment which now serves as a model for all similar enterprises throughout the country. Last year the school was incorporated and Colonel Auchmuty and his wife, in addition to the previous gifts, presented the sum of $100,000, J. Pierpont Morgan at the same time donating $500,000; so that the institution now stands on a firm basis, and will endure as a noble memorial of its founder and benefactor. "The Colonel," as he was

always called by the students, worked hard in the management of the school, which he was accustomed to visit almost daily, talking to his "boys," imparting kindly advice, and receiving their confidence and affection in exchange. Singularly winning in manner, with a kindly tact and generous, broad mind, all who came in contact with him formed a respect and admiration for the man; and many a youth has testified to the benefit which the colonel's personal influence worked on his life. Colonel Auchmuty also assisted materially in founding the mechanical trade schools of the Builders' Exchange in Philadelphia, to which he contributed $3000 a year for the first three years of its existence. Often urged by his friends to stand for public office, he always declined on the plea that his time was too fully occupied in the management of his beloved trade school. Colonel Auchmuty was a vestryman of Trinity Church, New York, and a trustee of the Cathedral of St. John the Divine, and was active in many good works in this city and in his summer home at Lenox. Always modest and retiring, he was little seen in fashionable gatherings, but among "his boys" he found his truest happiness.

The following editorial notice of the late Colonel Auchmuty appeared in the New York *Evening Post* of July 19:

In the death of Col. Richard T. Auchmuty this city loses a model citizen and the nation a benefactor. He was of such unfailing modesty, his work was performed always with such studied avoidance of all ostentation, that few persons except those within the immediate circle of its influence had much knowledge of its vast importance. Yet he was one of the most potent agencies for good in his time, and he has left behind him, thoroughly established on a strong and lasting foundation, a system of instruction for American youth which is destined as the years go by to spread over the whole country and to become of incalculable benefit to all the people. This is not the extravagant language of unrestrained eulogy, but the simple statement of the truth.

Soon after the close of the war, in which Colonel Auchmuty had performed meritorious service, he began as an architect to consider the question of technical or trade education in this country. He saw that the labor field in the United States was coming every year more completely into the possession of foreign laborers, who were getting control of all the trade unions and were using their power to exclude American-born boys from the labor field. Year by year the trade union regulations in regard to apprentices became more and more stringent, until they practically excluded American boys from the trades. At the same time, foreign workmen were admitted freely to all the trade unions, without much regard to their proficiency and with no regard to their character. The more Colonel Auchmuty studied this situation, the more profoundly was he impressed with the grave peril which it involved for the American people. He saw American boys growing up in idleness, their lives ending in crime and pauperism. At the same time he saw our labor field passing into the control of turbulent foreign elements, some of them even anarchistic in their tendencies, and the great majority of them without either knowledge of or sympathy for American institutions or social laws. Sooner than any other man of his time, perhaps, Colonel Auchmuty saw the peril which lay in this condition of affairs. We were neglecting to train citizens of the most desirable class in any nation—that is, self-respecting, honest, industrious workingmen, and in their places were admitting hordes of foreigners, all of whom were from the nature of the case destitute of the instinct of patriotism, and many of whom scorned the idea of cultivating it by adoption.

His intimate friends alone know how deeply a sense of the dangers lurking in these conditions sunk into Colonel Auchmuty's mind. He studied into the trade question in other countries, and saw that in all the nations of Europe there had been a somewhat similar problem presented and solved. There, as in the United States, the old apprentice system had passed away, the cause being the same everywhere. These were mainly the subdivision of labor brought about by the introduction of machinery, and changed social conditions under which a taint of servility had come to be attached to the apprentice relation. A boy could no longer be taken in a trade and taught the whole of it, for the foreman or master mechanic in most cases had supervision of only a single branch of it. European nations met the new situation by establishing technical or trade schools. They began to do this early in the present century, Germany, Russia, Belgium and Switzerland leading the way. France came early into the field, and England soon after her. To-day every nation of Europe has a system of trade schools. In Germany and France some other technical education is compulsory and a child is put through a regular system of technical instruction which culminates in the perfect trade school, whose graduates command journeymen's wages immediately upon graduation.

Colonel Auchmuty saw that we must, like Europe, find our remedy through education, but that we could not do this, as most European nations had done it, by means of State aid. We must do it with private funds, and he was always confident that by doing it in this way we should command the best results. He accordingly set the example, but without a particle of noise, by establishing his New York Trade Schools in 1881. He did this with his own money. From small beginnings they grew until he had invested $70,000 in them, and he and his wife had given in addition $160,000 as an endowment fund. During the first year he had 30 pupils, during the second 98, during the third 207, and so on by steady increase till at present the graduates number over 600 a year. The boys come to the schools from all parts of the United States and Canada. Practical instruction in various trades, such as plumbing, plastering, stone cutting, painting, bricklaying, carpentering and printing, is given by master mechanics and other competent teachers, and the instruction is accompanied when necessary by the study of technical books and trade papers. The end sought is "to enable young men to learn the science and practice of certain trades thoroughly, expeditiously and economically, leaving speed of execution to be acquired at real work after leaving the school."

From the outset Colonel Auchmuty met with the opposition and ill will of the trade unions. They would not admit his graduates, and they boycotted them when they tried to work without union cards. Then he, as an architect, put up blocks of houses to give the boys a chance to show what they could do, and some of the finest specimens of good workmanship in the way of building are to be seen in apartment houses and other structures which he had built in this way. After a time some of the trades unions treated his graduates better, but the great bulk of them remain hostile to this day. The Colonel was never weary of talking of his "lads," of showing the photographs of the members of his graduating classes, who, he said, with entire truth, compared favorably in appearance with the graduates of our colleges. They are a broad-browed, manly-looking set of young men, who are the kind of citizens every country ought to develop by every means in its power.

About a year ago, Colonel Auchmuty's schools were put forever beyond the experimental stage by a munificent endowment fund of $500,000, presented to them by Mr. Pierpont Morgan. The colonel felt then that the success of his work was assured. He had been laboring quietly with his voice and pen, and the good example he had set here had begun to find imitators in other cities. Soon after this his last and most painful illness fell upon him, and though he was hopeful till the end, he was not sanguine of recovery. He said frequently during the weary months in which he was shut up at home and unable to go to his beloved schools, that he was in one sense grateful for his affliction, for it had shown him that his schools would go on perfectly well without him, and consequently would continue after his course was run.

So they will, and so will the noble and inspiring lesson in civic duty, in what Mr. Bryce calls "home patriotism," continue for many years to come. Colonel Auchmuty has sown the seed for a new generation of American workingmen, who are proud of their calling because masters of its technique, and who go abroad in the world as living exponents of the dignity of labor. These are the citizens the country needs in many ways, but in none more than in their ability to undermine and destroy the pestiferous and degrading domination of the latter-day labor apostles who are a libel upon honest workingmen everywhere. It is because Colonel Auchmuty has, as we firmly believe, laid the foundation for this great reform that we hail him as a national benefactor.

Peck Bros. & Co.

The house of Peck Bros & Co., with general office and factory at 125–137 Chestnut street, New Haven, Conn., and with showrooms in New York, Boston and Chicago, have issued a catalogue of plumbing and sanitary work which will take a high rank among the trade publications of the day. The volume, which was compiled by W. E. Hinsdale, consists of nearly 600 pages, 9½ x 12 inches in size, and is bound in stiff board covers with a gilt side title upon a black ground. The latter includes the name of the company, the date and an indication of the business in which the company are engaged. A feature of the publication which will be appreciated by the trade is a back title in plain gilt letters, consisting of the firm name. The opening pages are devoted to views of the works at New Haven and of the sales and showrooms at New York and Chicago. In compiling the volume it has been the aim to illustrate a line of sanitary fixtures adapted to meet the needs of advanced plumbing and the requirements of the plumbing ordinances enforced in many cities, as well as the varying tastes of the public, in the ornamental fixtures shown. In offering it to the trade

Messrs. Peck Bros. & Co. request architects specifying or plumbers ordering any of their goods, to use numbers designating the illustrations, and if it is desired to use any fixtures other than those shown in the complete article to employ the designating number of such fixture in connection with the main fixture specified. An alphabetical index occupies ten pages, following which is a telegraphic code for ordering goods by wire. The illustrations cover an almost endless assortment of sanitary fixtures, including lavatories, basin cocks, bibbs, brass fittings, couplings, elbows, hydrants, kitchen sinks, nozzles, nipples, plugs, porcelain goods, pumps, radiator valves, range boilers, reducers, sanitary earthenware, saws, screws, steam cocks, cast iron fittings, street washers, stops, tanks, tees, traps, water-closets and tanks, steel range boilers, wrenches, wrought iron pipe, couplings, &c. A very handsome feature of the publication is a number of pages showing a variety of decorations of closets, both on plain and on embossed bodies. These designs are carefully printed in a way to show the closets as they actually appear, the decorative features being worked out in an artistic manner. The same may be said of decorated basin cocks and of decorated basins, of which many designs are shown. The catalogue carries, in addition to the illustrations, brief descriptive particulars as well as numbers and prices. Its general make-up shows evidence of careful attention to details and due consideration of the requirements of the trade. The publication is highly creditable of the house issuing it, and we have no doubt that every one into whose hands a copy may come will duly appreciate it.

The Education of the Craft.*

The subject allotted to the delegates from the city of Los Angeles, Cal., through the kindness of your Essay Committee, is one which demands the attention of every master plumber in the world; for upon "the education of the craft" depends almost entirely the future prosperity and status of sanitary science.

It is a recognized fact that the National Association of Master Plumbers should enforce an apprentice system, whereby the apprentice would be enabled to educate himself in the art of plumbing. It should be the duty of this association to inaugurate technical schools for the art of plumbing in all the larger cities, and encourage the use of periodicals and standard works on the same, for the education and benefit of the craft.

To the masters I would say, be more particular in selecting your boys. Insist upon it that they be respectably connected. They should have a good common school education, be possessed of a mechanical turn of mind, combined with good reasoning faculties, as well as a spirit of independence that will at all times enable them to act for themselves. They should have a good physical constitution and be prepared to serve a regular apprenticeship for five years. Their moral qualifications must also be of the highest order.

After having decided upon an apprentice system, each local Master Plumbers' Association should appoint a committee for their examination semi-annually, and great care should be taken to invite apprentices from surrounding villages to these examinations, which should determine their qualifications. The committees should compile their own list of questions, as climatic differences affect the art of plumbing.

The journeyman's qualifications should comprise a correct knowledge of the laws of governing the motion and action of the various substances, both fluid and solid. This renders a knowledge of hydraulics, hydrostatics and kindred subjects quite indispensable. The knowledge of drawing will also be found of great service. The journeyman should be more friendly to the apprentice. The existing ill feeling is degrading to the business. By treating him in such a manner he will not only raise the standing of himself and his trade in the opinion of the public, but make it more valuable from a selfish point of view.

The journeyman, after having received his diploma, should practice the art of plumbing for a period of one year, when, if desirable to him, he should be entitled to an examination as a master plumber. This examination to determine his qualifications should be held annually by examiners appointed by the Federal Government, and balloted for by the National Association of Master Plumbers at their convention held in the year preceding presidential election, and should hold office for a period of four years. No one should be eligible unless he had served at least five years aside from his apprenticeship. A bill to this effect should be presented to the next Congress, as it is a national question and should be dealt with accordingly.

While State and city laws have done much good, we all know that health commissions of this kind are usually manipulated by the wire-pullers, and men who have absolutely no ability receive the appointments. The result is that the responsibility of the sanitary condition of the world depends entirely upon the plumbers. Therefore, gentlemen, I ask you why we should not have credit for what we know, and why are we not entitled to a national law for examination and registration of master plumbers, showing that educated master plumbers are the responsible sanitary engineers of the day? If each member of this convention will consider himself a committee of one to secure the passage of such a law, we will accomplish more for the education of the craft than in any other manner.

* Submitted by the Los Angeles Local Association at the Milwaukee Convention of the National Association of Master Plumbers, June 13-16, 1893.

THE VIRGINIA PLUMBING AND HEATING COMPANY have been incorporated at Richmond, Va., to manufacture and deal in heating and plumbing materials. G. W. Priddy is president; C. E. Bare, vice-president; and C. A. Huffmann, secretary and treasurer.

Straits Tin.

The store of tin in the mines of the Straits is said to be practically inexhaustible. A recent report from that district says that, in the opinion of practical men, these mines have been only superficially prospected so far. As more than half the tin supply of the world is obtained from the Straits, scarcity of the metal need not then be feared. The output of the mines has steadily increased of late years, and the increase is likely to continne. The folfowing figures show the exports in tons:

1887	27,549
1888	29,169
1889	33,021
1890	31,976
1891	36,061

For the years 1890 and 1891 the principal shipments from the Straits, by countries, were as follows, the picul being 133⅓ pounds:

	1890. Piculs.	1891. Piculs.
United Kingdom	267,238	293,024
Austria	5,295	4,035
France	40,935	45,446
Germany	2,102	2,532
Holland	14,304	18,355
Italy	3,698	6,676
United States	118,243	1683,647

These figures show a marked increase in the shipments to the United States, which may be attributed to the establishment of the tin-plate industry in this country during the latter half of 1891.

SCRAP.

IN A CIRCULAR recently issued the St. Louis Stamping Company, St. Louis, Mo., call atttention to their American tin and terne plates, which they claim to be, in toughness and softness, fully equal, if not superior, to the imported article. All the tin plates made by the firm are guaranteed to stand double seaming without breaking.

THE LONG-CONTINUED DROUGHT in Britain is being felt at the Welsh tin-plate works, several of which have been obliged to partially suspend operations for lack of water.

AT THE PONTARDAWE TIN PLATE WORKS of W. Gilbertson & Co., near Swansea, Wales, a strike has occurred among the whole of the tin house men. The dispute at the Carmarthen Tin Plate Works appears to be still unsettled, and the men remain out. The burning question is the infliction of fines for breakages.

A NEW TIN-PLATE WORKS of ten mills is to be erected at Kidwelly, Wales.

THE TIN-PLATE MARKET is reported as still very quiet in England, American orders being light, owing to caution in the purchase of stocks, while the action of Congress in respect to the Tariff remains doubtful.

TIN PLATE WORKS are in operation at Piombino, Italy. The labor is mainly supplied by Welshmen.

THE CHICAGO TIN PLATE COMPANY of Chicago were recently incorporated with a capital stock of $25,000 for the manufacture of iron and steel sheets and tin and terne plates. The incorporators are J. C. Benton, C. D. Miller and N. D. Lewis.

C. R. BRITTON of the Cleveland Tin Plate Company has taken charge of the tin and terne exhibit at the World's Fair for a few weeks.

RITER BROS. & Co., Philadelphia, will be found out among the trade now that the patriotic tinner has resumed labor after his celebration. The demand for their varied brands of tin and terne plates has been satisfactory during the early part of the year.

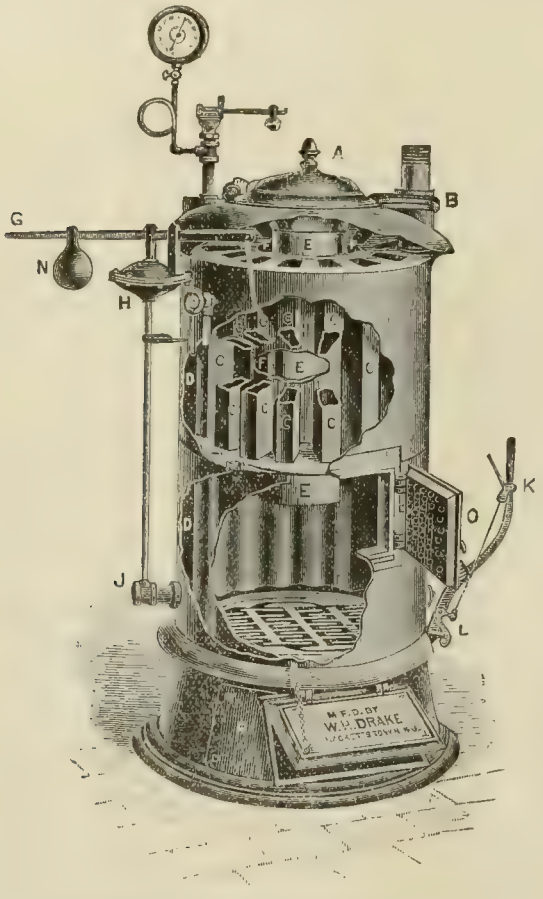
Much damage has been done and much suffering caused by the recent droughts in Germany. The peasantry have lost most of their young crop and the scarcity of fodder is becoming a national calamity. Cereals have been purchased with State funds to aid peasants and feed their cattle.

Experiments are shortly to be carried out by the Navy Department to determine the best colors to paint war ships in order to make them as difficult as possible to sight at sea.

STEAM AND HOT WATER.

The Torrid Steam Heater.

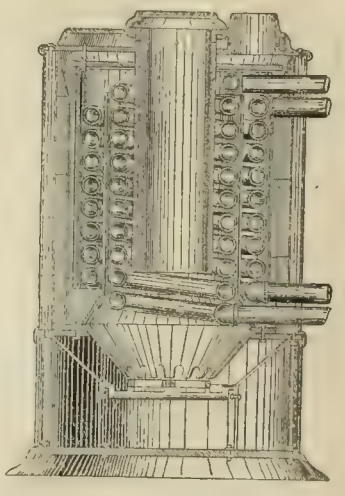
W. H. Drake of Hackettstown, N. J., is offering the trade a steam heater known as the "Torrid," and which is represented in sectional view in the accompanying engraving. The heater, which is entirely of cast iron, is made in two sections, the lower forming the fire box, while the upper has the flues cast in one and the same piece with the shell and the heads. The flues are upright, leaving no place, the manufacturer states, for the accumulation of dust and ashes, and also are absolutely without joints. The sections are placed one above the other, and in this position holes through which the water and steam pass from the lower to the upper sections are reamed and tapped, while a hydralic nipple is firmly screwed into the openings, thus making a perfectly tight joint. As the weight of the upper section rests on the lower section, the nipple connections are free from strain. In offering this heater to the trade the manufacturer refers to its durability and economy, as well as its ease of management and handling. It has rocking and dumping grate, is tested to 200 pounds and occupies comparatively little space in the cellar, or wherever it may be placed. Referring to the sectional view presented herewith A is the swing cover under which the coal is placed in the feeder; B is the hinge of the swing cover around the main steam pipe; C C C are upright flues around which the water circulates; D is the water space; E the magazine; F the fire flue around the magazine; G the lever for damper regulator; H the damper regulator; J the main return pipe; K the rocking lever and latch lever; L the latch to hold the grate bars in position; N the weight to regulate the draft; O the front feed door, and P the removable section on the base to admit the grate. The Torrid is adapted for steam or hot water, and is now made in six sizes, having grates measuring from 9 to 21 inches in diameter, and adapted to supply steam for 100 to 1000 feet of radiating surface. A special feature of the heater is the regular upright tubular boiler, combining the advantages of the ordinary wrought iron tubular boiler with those of cast iron for heating purposes. All sizes are made direct draft and return flues. In the latter the products of combustion after passing up through the tubes are carried down around the outside of the boiler, thus utilizing to the fullest extent the heat generated in the fire box. The return flue heaters may be readily converted into direct draft by turning a single damper. All sizes are made so that they can be used either with magazine, self-feed or as surface burners.



Broken View of the Torrid Steam Heater.

The Gurnee Hot Water Heater.

P. J. Gurnee, Kingston, N. Y., is making an improved hot water heater especially adapted for use in connection with dwellings, churches, greenhouses, &c., and which is shown in vertical sectional view in the accompanying engraving. This heater consists of two steel cylinders, one within the other, while the space between the two is filled with a non-conducting material. Within the inner cylinder is a fire pot which, with its connecting self-feeding coal magazine, has a capacity of burning many hours without attention. In this apparatus the water is heated in coils of steel pipe, placed within the inner cylinder, the pipes employed for connection with the radiators being about the same size as those in the heater. This arrangement, the manufacturer states, gives a free circulation of the water. The coils are placed directly over the fire pot, and the water being confined in a small space rapidly becomes heated and immediately establishes a circulation. The maker states that with this heater the fire may be crowded as much as desired from the very start, without danger of cracking or explosion. In offering this heater to the trade Mr. Gurnee refers especially to several points, among which may be mentioned durability, safety, portability, ease of management and also to the fact that the heater can be placed in a basement dining room and when bronzed is as ornamental as a stove.



Sectional View of Gurnee Hot Water Heater.

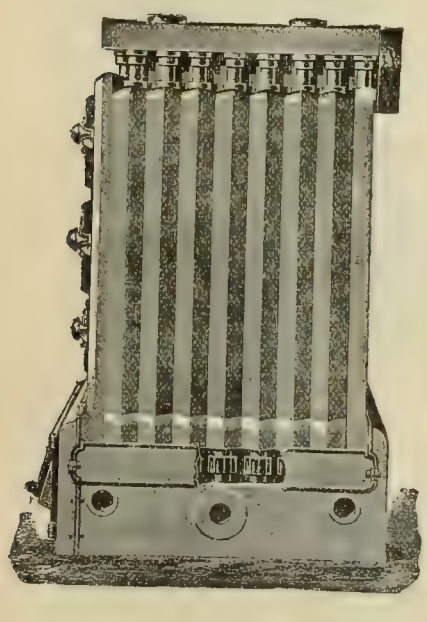
The Gurnee heater is made in four sizes, with fire pot from 16 to 28 inches and heating capacity from 12,000 to 60,000 cubic feet.

Geo. B. Cobb & Co., New York and Philadelphia, have just issued a neat pamphlet of the "Florida system" of heating, containing a number of half-tone engravings of handsome residences, flats, churches, hotels and office buildings in which their system has been used. It treats briefly of the different artificial heating methods, recommend-

ing steam and hot water, the installation of such plants being their specialty. The advantages of their system and the different kinds of radiation are explained, while numerous testimonials show the satisfaction their goods have given.

Capitol Hot-Water Heater.

The accompanying engraving shows the 1893 pattern of the Capitol hot-water heater, manufactured by the United States Heater Company, Detroit, Mich. No change in the main features of construction have been found necessary, as the record of the heater for efficiency during the severe weather of last winter is said to have been all that could be desired. The grate and the shaking arrangement have, however, been improved, and the fastenings of all the doors changed. In the new pattern there is sufficient space between the front of the heater and the next intermediate section to permit soot and ashes, when brushed from the inner surfaces, to fall into the fire pot, thus preventing their escape into the cellar. As shown by the side view, the smoke pipe will here-



Side View of 1893 *Pattern of Capitol Heater.*

after be taken out at the rear of the heater instead of extending up above the top, thus permitting the heater to be placed in lower cellars than was formerly possible. The side plate, which formerly covered the top connections, will now be inside of those connections, so that they will not be exposed to the heat of the fire. These little points, while not affecting the general operation of the heater, are designed for the convenience of the fitter, and as such will no doubt be appreciated.

Heating and Ventilation of the Imperial Institute, London.

The heating and ventilation of the newly-inaugurated Imperial Institute in London is said to be carried out on the most improved modern principles. The general arrangements are thus described by an English exchange:

Nearly the whole of the basement area of the front building is formed into air chambers under the basement floor, with a sub-basement corridor running the whole length, and fresh air is brought into these chambers from the outside atmosphere at 32 different places, where it is filtered and moistened by passing through a water spray. In the winter it is warmed in its passage over a series of gilled steam pipes, and thence conducted to the various rooms in vertical ducts, discharging itself through air valves in the chimney breasts controlled by regulators.

The whole of the warming is by steam, and the mains to the various heating chambers are carried in the subway, where they are fitted with control cocks to each several section under the immediate supervision of the engineer, enabling him readily to regulate the amount of heat without the necessity of going into the building. The fresh air admission valves are also worked from the subway, by which the quantity of fresh air which is admitted can also be regulated. The whole of the corridors and galleries are warmed by steam radiators, provided with fresh air ventilating tubes through each pipe, and having fresh air admitted to the bases from the outside atmosphere.

The vitiated air is taken from every room and corridor by means of extraction shafts built in the walls, and fitted in the room with self-acting floating valves. The whole of these shafts are connected into four main trunks or ducts in the roof, and are carried to the center tower, where they discharge into the open air. To facilitate the extraction of this vitiated air a pair of engines with a compressed air plant and receiver is fixed in the general engine house, and the compressed air is taken to the roof and coupled up to the main trunks in several places, and the end of the pipes fitted with gun metal nozzles for inducing a rapid outflow of the atmosphere of the rooms into the outer air and cause a constant renewal of the fresh air passing through the various rooms, warmed in the winter and cooled and moistened in the summer.

HEATING NOTES.

George H. Reynolds, secretary of the Master Steam and Hot-Water Fitters' Association of the United States, announces that the headquarters for the ensuing year will be at Room No. 625 Metropolitan Life Insurance Building, Madison avenue and Twenty-third street, New York City.

Sealed proposals will be received at the office of the Supervising Architect at Washington, D. C., until July 27 for all the labor and materials required for repairs to the heating apparatus of the United States Treasury Department Building, Photograph Gallery of the Treasury Department and the Winder Building at Washington, D. C., in accordance with the specification, copies of which may be had from the office of the Supervising Architect.

The Richmond steam and hot-water heaters are considered in a little pamphlet which has been issued by the Richmond Stove Company of Norwich, Conn. The merits of these goods are clearly set forth, while a long list of testimonial letters show the favor with which they have been received by the trade.

The American Boiler Company of Chicago, Boston, New York, Denver, San Francisco and Portland, Ore., are distributing a very neat advertising device in the form of a postal card with a small United States mail box attached to its back, part of the usual lamp post being seen above and below. In the mail box is a circular entitled "Use the Mails." The suggestion is made to the trade that this is the time to distribute circulars and catalogues among prospective customers. The company will be pleased to provide catalogues to those who desire them for this purpose.

The Fowler Radiator Company, 435 N. Broad street, Philadelphia, Pa., are sending out a sheet of the Fowler radiators. The features of the goods are clearly set forth, the Fowler complete semi-direct radiator being the leader.

The Bennet & Peck Heating and Ventilating Company, Cincinnati, Ohio, are installing a complete system of heating and ventilating in a new school building at Sewickley, Pa., which embraces all of the latest ideas in the art.

The Boland Trade Schools.

The new building which is to house the trade schools connected with the Roman Catholic Orphan Asylum on Madison avenue, between Fifty first and Fifty-second streets, New York, is now approaching completion, and it is expected that it will be ready for occupation by September 1. The building is a handsome structure, occupying a space of 200 feet by 56 feet, and is constructed of red brick with brown stone facings. It comprises three stories and a basement, the latter devoted to the class rooms for manual instruction, and the upper floors to the accommodation of the pupils, all of whom will live on the premises. It is calculated for the training of 100 to 150 boys, and all the mechanical trades usually taught in such schools will be represented in the curriculum. It is proposed to copy closely the Auchmuty system of instruction as conducted in the New York Trade School. Plumbing, carpentry, painting, plastering, machine work, bricklaying, and other trades are being arranged for, the instructors for which will be drawn from the trades in the city.

These schools are the outcome of a bequest of $50,000 left some twenty-five years ago by William Boland of New York for the establishment of a school for manual training of the older boys in the R. C. Orphan Asylum. The money was applied to the purchase of a farm at Peekskill, N. Y., where manual training has been given to the lads under the superintendence of the Christian brothers; but it has been found to be too remote from the city and too expensive to maintain. Consequently the present building has been provided at a cost of about $200,000. The boys will be taken from among the older lads of the orphan asylum, and they will be trained for manual trades, which they may eventually become perfected in by a course at some more advanced trade school.

A novel case has been taken to court by the people of Ironwood, Mich. The engineer in charge of the water works permitted dead fish, birds and other matter to putrefy at the bottom of the stand pipe through which the water for the city is pumped. An epidemic of typhoid fever resulted. The city now proposes to ascertain the legal responsibility of the engineer for the consequences of his neglect of duty.

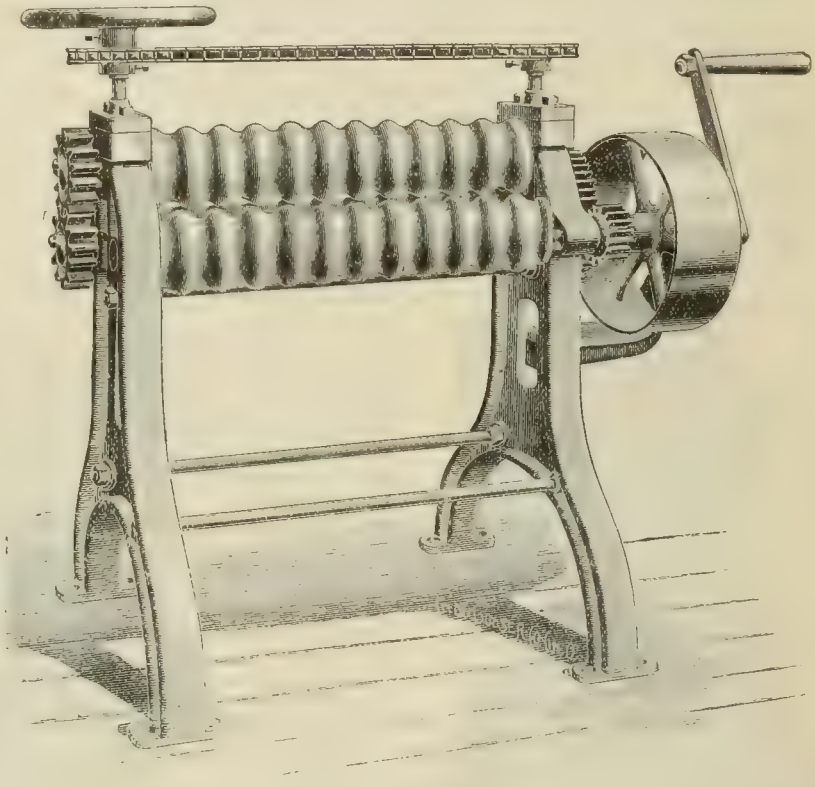
ROOFING AND CORNICE.

National Iron Roofing Association.

According to previous announcement made in these columns, the semi-annual meeting of the National Iron Roofing Association was held at the Hotel Plaza, Piqua, Ohio, on Tuesday, the 18th inst. Among the concerns represented were: S. D. Hicks & Son, Boston, Mass.; Kanneberg Roofing Company, Canton, Ohio; J. H. Eller & Co., Canton, Ohio; Canton Steel Roofing Company, Canton, Ohio; Garry Iron & Steel Roofing Company, Cleveland, Ohio; Standard Iron Company, Bridgeport, Ohio; Wheeling Corrugating Company, Wheeling, W. Va.; American Roofing Company, St. Louis, Mo.; Cincinnati Corrugating Company, Piqua, Ohio; James A. Miller & Brother of Chicago and W. G. Hyndman & Co. of Cincinnati, Ohio. The proceedings were conducted with James Hicks of S. D. Hicks & Son in the chair. The time was largely occupied in adapting the weights on painted and galvanized roofing to conform to the new United States standard gauge. While the members of the association were in Piqua they were handsomely entertained by the Cincinnati Corrugating Company and by the citizens of the place named, a banquet being one of the prominent features.

New Curving Machine.

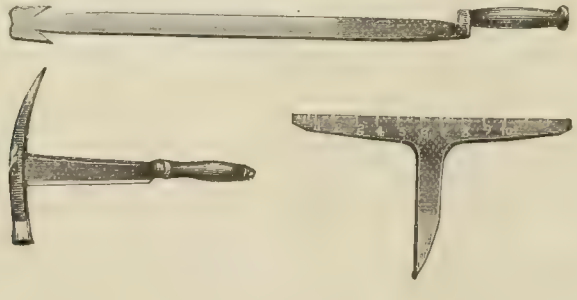
In the accompanying illustration we present a general view of new and improved curving rolls, which have been brought out by J. M. Robinson & Co. of Cincinnati, Ohio. The machine having been especially designed for arching, curving and forming corrugated sheet metal. The rolls may be operated by steam or hand power according to convenience. Special reference is made by the manufacturers to the fact that while the rolls are in motion and a sheet of metal between them they may be reversed, thus continuing the travel, back and forth, of the corrugated sheet in the process of being formed, and this operation may be carried on until the required formation is secured. This feature is considered of great importance by the manufacturers, as it results in the saving of time and insures the perfect forming of the work in hand. The machine is composed of three grooved rolls, two being at the bottom and one at the top. The bottom rolls are made on a horizontal line, running parallel, and the sides touching. The center line of the top or forming roll is directly over the point of contact of the two bottom rolls, all of which are properly geared together, so that power applied to the crank or pulley will set all in motion. The position of the top or forming roll, the manufacturers state, permits the forming of arches of small radii up to the largest required for work in general. The movement of the top or forming roll for graduating the radii is accomplished by means of a chain belt running from a sprocket wheel secured to the hand-wheel shaft on to another sprocket wheel secured to a shaft connected with the opposite end of the roll. By this means a parallel adjusting movement of the top roll is secured by simply turning the hand wheel in either direction, according to the nature of the work under way. The width or pitch of the roll grooves must correspond with the corrugated sheet to be formed, the usual pitch of which is 2½ inches. From an inspection of the engraving herewith presented, it will be seen that the rolls are properly journaled and supported in heavy standards, thus imparting strength and rigidity, while preventing possible chance of springing while in action.



New Curving Machine.

Set of Slater's Tools.

Illustrations are herewith presented of a set of slater's tools, such as are now being manufactured expressly for the Illinois Roofing & Supply Company, 203 Lake street, Chicago. One hammer, one ripper and one stake constitute a set. The hammers are perfectly balanced and made of best steel, with leather handles to prevent the hand from slipping. The rippers are strong and durable, made entirely of forged iron and steel. The stakes are properly constructed and made of forged iron and steel.



Slaters' Tools.

FLASHINGS.

ONE OF THE SUFFERERS by the burning of Hercules Iron Works Cold Storage Building at the World's Fair grounds on the afternoon of Monday, July 10, was W. H. Mullins of Salem, Ohio. The fire destroyed the magnificent statue of Columbus, recently turned out by Mr. Mullins and which stood at the main entrance to the building. Although the statue was destroyed, we understand that there are three others in existence, made from the same model, one adorning the park at New Haven, Conn., another in the grounds of an art school at Columbus, Ohio, and the third at Phillipsburgh, N. J.

GILBERT HOWELL of Piqua, Ohio, will have the deep sympathy of a wide circle of friends in the death of his wife, which occurred on the evening of Friday, July 7, after an illness of several weeks. Mr. Howell is secretary of the Lucas & Barnett Company at Piqua, Ohio.

THE LYCOMING METAL WORKERS' ASSOCIATION of Williamsport, Pa., has recently been organized for the protection of mutual interests and the maintenance of better prices for metal work. We understand that those interested met and formulated a scale of prices, by which all agreed to be governed. We are informed that the association is working satisfactorily, and that prices are better and the trade furnishing better goods than heretofore.

MERCHANT & CO. of Philadelphia have recently shipped several carloads of their copper shingles to the Pacific Coast, where they are to be used on some of the largest buildings in Portland, Seattle and Tacoma. They have also shipped a quantity of the shingles to Lexington, Ky., and Atlanta, Ga., for use on two very important buildings in those cities.

WE ARE INDEBTED to Eberts Brothers Company, Limited, 192–198 High street, West, Detroit, Mich., for a copy of an interesting pamphlet entitled "Summer days on the Detroit and St. Claire Rivers." The little volume is profusely illustrated with photo-engravings of buildings and places of interest on the rivers named, as well as at Oak Grove, Port Huron, the St. Claire Flats, Oakland and Grande Pointe. Scattered through the pages are numerous advertisements, among them being that of Eberts Brothers Company, in which attention is called to roofing of various kinds, corrugated iron for sidings, ceilings, doors, shutters, awnings, &c., as well as to roofers' sundries.

JAMES L. FOOTE, manager of the Slatington-Rangor Slate Syndicate, is reported by a local paper to have expressed the opinion that the slate industry, as a whole, was in advance of previous years, and that the outlook for the remaining months was very bright. It is stated that the syndicate shipped in the month of June 121 carloads, embracing 5874 squares, besides several cars of blackboards and milled stock. It is said that orders already booked for shipment in July aggregate more than 7000 squares. Large shipments are being made to the far West at points in Iowa, Kansas, Missouri, Nebraska and Colorado.

ALL TRACE of the fire at the American Roofing Company at Cincinnati, Ohio, has been cleared away, and the old site is occupied by a splendid new building 60 x 200 feet and three stories high. The office is on the second floor and, of course, has a handsome metal ceiling of their own manufacture, while the side walls, columns and girders are covered by ornamental sheet-iron work. One end is used to display samples of the various styles of roofing and corrugated, imitation brick and clapboard siding. The first and second floors are equipped with corrugating machines, rolls, brakes, shears, stamping presses, folders, lock seamers and all necessary machinery, made by George C. Keene & Co., and installed as arranged for by James McCarty, the superintendent. A railroad siding is in front of the building and a small railroad with switches runs through the building out to the siding, so that material can be unloaded on their trucks and brought to any machine or stock pile as desired. The trucks are hauled about the building by means of a rope which is wound about a friction spool which is turned by the engine. At the rear on one side is the engine and boiler, and on the other side of a substantial wall or partition is a fine stable for several horses and wagon storage with labor-saving devices for feeding and watering the horses and washing the wagons. The third floor is used for lighter work and storage of manufactured goods of ornamental character.

AN ORNAMENTAL FEATURE of the Hospital Building at Seattle, Wash., will be a roof of Spanish metal tiles, a carload having just been furnished for that purpose by Merchant & Co. of Philadelphia. They are also preparing to ship three carloads to Portland, Ore., as their Spanish tiles have been specified by Architects Van Brunt & Howe of Kansas City, Mo., for the roof of the new terminal depot in that city. These tiles are finding much favor, owing to the high relief afforded by the design giving an effect equal to the old earthen tile, while besides being durable the building is relieved of a great load, the weight being only about one-third that of tile. Liberal use has been made of these copper tile in buildings on the World's Fair grounds, and a more general use of them is expected where an ornamental roof of superior quality is desired.

WE ARE INDEBTED to W. H. Mullins, Salem, Ohio, and with Eastern agency at 108 Chambers street, New York, for a copy of a very attractive catalogue which has just been issued from the press. The volume is oblong in its general shape and consists of 76 pages of profusely illustrated matter, bound in paper covers. The work shown is made by steam-power machinery and is sufficiently varied to meet the requirements of architects, builders and all having to do with building construction and sheet-metal work. The assortment includes building fronts, galvanized-iron cornices, window caps, wrought and tubular iron awning supports, office railings and fixtures, stair rails, finials, galvanized iron and copper crestings and terminals, iron siding, chimney tops, embossed sheet-metal ceiling, Kinnear's patent lock rib roofing, galvanized iron skylights, and a long list of stamped zinc ceiling center pieces. The catalogue is so arranged as to be of easy reference and in connection with the design presented are given such particulars as the would-be purchaser is likely to require in order to make himself intelligent concerning the goods illustrated. In directing the attention of architects and builders of the country to this publication special reference is made to the fact that in the way of cornice work the manufacture has deviated from old trodden paths and brought out artistic productions of correct proportions and of a character which has not heretofore been attempted in this branch of building construction. The cornices are all made in large sections with brackets, medallions, panels, &c, connected and put in such shape for transportation that any tinner, carpenter or mechanic of ordinary skill can readily put them in position. All work turned out by Mr. Mullins is of the best quality of material and in the very best manner known to the trade.

SOME of the recent shipments by Geo. C. Keene & Co., Cincinnati, Ohio, have been a 23,000-pound corrugating machine to the Wheeling Corrugating Company, at Wheeling, W. Va., which is the third made for them; a cornice brake to the Phœnix Plumbing Company of Phœnix, Arizona; a punching machine to punch ¼ inch holes in No. 10 iron to J. F. Dean, Salem, Mass.; a range maker's flanging machine to the Buck's Stove & Range Company, St. Louis, Mo.; a 10-foot corrugating machine, weighing 11,000 pounds, to the Cambridge Roofing Company, at Cambridge, Ohio; and a machine of the same size to the American Corrugating Company, St. Louis, Mo.; while cornice brakes, from 4 feet to 10 feet, are sent to all sections.

Prize Competitions.

THE COMMITTEE to whom the contributions in Prize Competition No. 18 were referred have awarded the prizes as follows:

First Prize to L. TIFF RISK.
Second Prize to DANIEL P. HOLMES.
Third Prize to RICHARD DAVIES.

House Ventilation for Hot Climates.

A new method of house ventilating suitable for hot climates, the invention of W. B. Gwyther of the Indian Public Works Department, is described as follows by a London exchange: The object of the invention is not only to prevent the penetration of heat through the roof or damp through the floor, but also to provide a means of carrying away heated and vitiated air from inside. The method consists in the use of hollow tubes of earthenware; in the case of flat-terraced roofs these are employed as a substitute for ordinary flat tiles which support the roof concrete. The tubes are laid closely side by side, and, where they meet end to end, a cross flue to secure more perfect ventilation is formed by the use of half pipes. The ends of these flues when feasible should be provided with iron gratings for the ingress and egress of air; the ends of the hollow tubes where they rest on the wall should open into a longitudinal flue made in the wall. Where lateral openings or gratings cannot be arranged, vertical openings through the roof, covered with bent pipes, may be resorted to as an alternative. To draw away the vitiated air from below, perforations in the under side of the tube have been devised. The efficacy of these openings in removing air from the upper part of rooms rests on the fact that heated air moves upward, and after passing through the small apertures, will be carried off through the tubes and cross flues, within which a movement of air will always be going on. In the case of floors the prevention of damp can be effected very thoroughly by the doubly ventilated space.

THE TIN SHOP.

Sheet-Metal Boats.

From E. B. R, *Rising Sun, Ind.*—Please advise me through the columns of *The Metal Worker* concerning the general details and patterns required to construct a skiff. The skiff is to be made of galvanized iron.

Answer.—In complying with our correspondent's request and at the same time offering to those of our readers who may be interested some practical information on the subject, the accompanying design is given.

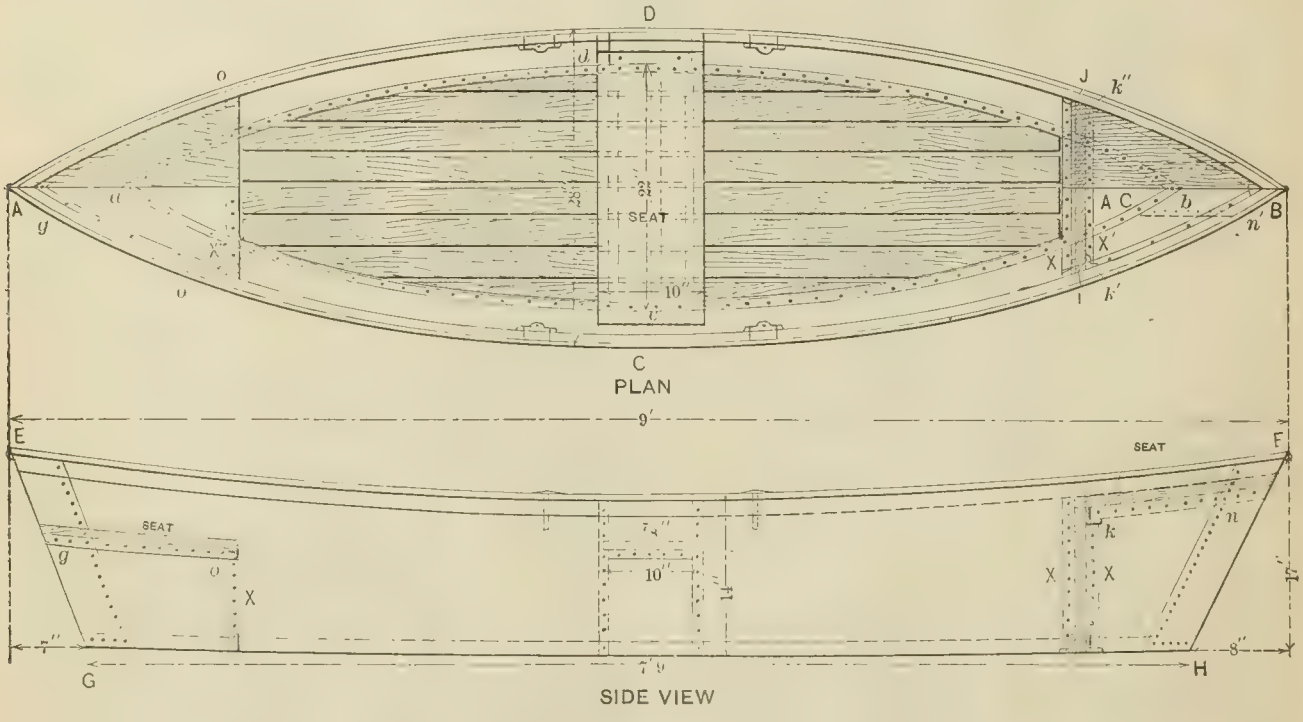


Fig. 1.—Plan and Side Elevation of a 9-Foot Skiff.

SHEET-METAL BOATS.

Although for some of the details entering into the construction of the boat wood is made use of, this feature is not present to the extent that it would require the assistance of an expert shipwright to build the boats. For the seats, bulkheads and strips used to stiffen certain parts of the boats, wood, as a matter of course, is the most suitable material.

In Fig. 1 A B C D represents the plan and E F G H the side view of a small skiff, 9 feet in length and 28 inches beam. The depth at each end is 17 inches, and amidships it is 14 inches. The bottom, across at its widest part measures 23 inches, and in length it is 7 feet 9 inches, or 15 inches shorter than the extreme length of the gunwale from E to F of the plan. The outline of the curve for the bottom is shown by the line *a c b* of the plan. At one end of the boat is an air chamber or life compartment, J I B. The boat is to be provided with three seats, one in the middle and one at each end. The general measurements given before for this style of boat can be changed to suit the builder, but we would not advise making the extreme length longer than 16 feet, and in width not more than 40 inches. A boat built to the measurements shown by the plan and side view, Fig. 1, will have a capacity to carry two persons comfortably, with about 150 pounds additional weight for baggage, &c. To construct the boat, either of the two following methods may be used: One is to get out the sides and the bottom first, then joining the parts together, after which construct the frame work, &c. If this method is used the patterns for the sides can be developed by triangulation.

The other and simpler method is, first, to get out the frame work, then placing the iron for the sides against the same, mark off the outline of the parts required, and then allow for laps. These particulars noted, proceed to construct the frame work. Commence with the bottom frame, making it of either ¾-inch or 1-inch angle iron according to what use the boat is to be put. If the skiff is to be made to the measurements given in Fig. 1, ¾-inch angle iron will do. Make the frame to the exact outline *a c b* and *a d b* of the plan, Fig. 1, arranged in the manner shown by A and B of the sectional view, Fig. 2. The bottom curve of the frame is to conform to the bottom G H of the side view, Fig. 1. The two ends *a* and *b* can either be bolted or if convenient they can be welded together. Drill or punch the holes for rivets through the angle iron about 6 inches apart on each wing, staggering them on the two wings of the iron. Countersink every rivet hole on the side of the angle iron against which the shell or iron is to lay, so that when the rivets are drawn and headed up, the outside will finish flush. Next get out the three braces X, X′ and X″, shown in plan and side views, Fig. 1. Two are required to hold the bulkhead J I in position and also to support the seat J I B. The other brace X″ is required to brace the boat, and is also used as a support for the seat at the other end.

The sectional view, Fig. 2, shows the shape of the braces. The brace X′ placed nearest the end B inside of the air chamber is to be made to form the circuit C D E and F shown in Fig. 2.

The brace X″ is to form the circuit G H E F. The brace X placed in front of the bulkhead J I is a trifle larger than brace X′, and is also made solid. The part C to D is used to fasten the seat. The three braces X, X′ and X″ are each to be fitted to conform to the position demanded for them by the plan and side view, Fig. 1. They are to be made of ¾-inch angle iron.

Space the rivet holes about 2 inches apart on those sides of the braces in contact with the iron sides and bottom of the boat. Through each one of the three sides of brace X′ in contact with the wooden bulkhead J I, punch three holes and countersink them so that the wood J I can be fastened to the brace X′ by short screws. Through the top parts of braces X′ and X″ in contact with the seats drill three ¼-inch holes to allow of the seats being fastened to them by ¼-inch bolts.

Then for the support of the seats from the braces X′ and X″ toward the ends A and B of the boat, make of ¾-inch angle iron the two supports *g o* and *k n* shown in the side view and plan, Fig. 1.

These supports are to be made solid and fitted from *o′ g′* to *o″* and *k′ n′* to *k″*, as shown in the plan, and are to be riveted to the sides on the inside of the boat. Space the rivet bolts about 3 inches apart and when punched countersink the holes on the outside so that the rivets by which the supports are fastened to the sides will finish flush.

The next part of the frame work to get out is the strips for the gunwale. If desired those used on the inside of the boat can be made of oak while the outer ones can be made of iron. Make the inner strips of ⅛ inch by 2 inch stuff, and the outer band of 1 inch half round iron.

Fig. 3 shows how the inner and outer bands are fastened together and also how the iron sides are lapped over the inner strip. First shape the two iron bands of the gunwale as demanded by the plan and side views, Fig. 1. To fasten the wooden and iron bands together use $\frac{3}{16}$-inch bolts. Space the holes for these bolts on the iron bands throughout their entire length about 6 inches apart. To fasten the ends of the iron bands together insert a small block of wood of the required shape between them, as shown in Fig. 4. Then fasten the ends together either by ¼-inch rivets of the required length or with bolts, as shown in Fig. 4. Next get out the four ¼ x 1¼ inch iron strips to be used for the supports for the center seat. How these are arranged is shown by the sectional and side views, Fig. 5, and the plan, Fig. 6, of the cuts. The section A shows the supports bolted to the bottom angle iron of the boat and also to the inner strip of the gunwale at the top. Underneath the seat is shown by *a* the end of a 2-inch angle iron through which a pin projects, used to fasten the seat to the same. A brace of wood is shown above the seat by *b*, this is shown bolted to the upright support and fastened to the seat by a wood screw. The side view B and the plan C show the described details so clearly that no further description of these parts is necessary.

After the entire frame work of the boat has been prepared and ready, set up and bolt the parts of the frame work together temporarily, in such a manner as to enable one to obtain the outlines of the patterns for the sides of the boat.

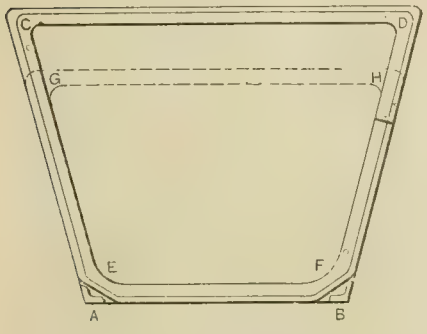

Fig. 2.—Cross Section, Showing Shape of Braces.

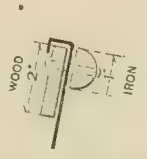

Fig. 3.—Section Showing Manner of Fastening Strips and Iron Band on Gunwale.

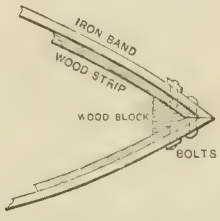

Fig. 4.—Fastenings of Gunwale Bands.

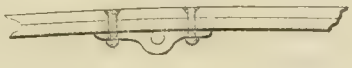

Fig. 7.—Method of Fastening Oarlock Fitting.

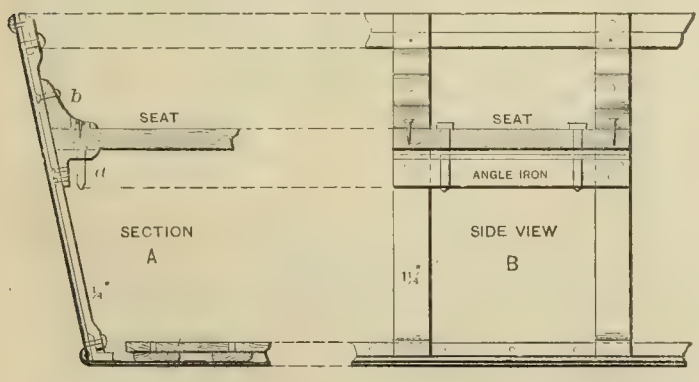

Fig. 5.—Section and Elevation of Middle Seat.

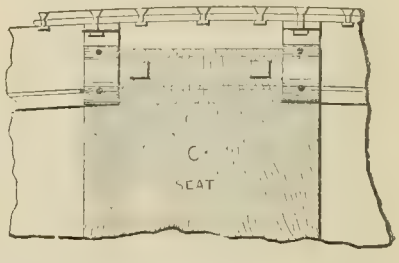

Fig. 6.—Plan View of Middle Seat.

SHEET-METAL BOATS.

To do this, bolt the braces X′ X″ to the bottom angle iron frame of the boat, also the four supports for the center seat. Then bolt in position the outer band of the gunwale by using the four center supports for this purpose. Then from some place near the ends A and B bolt a few strips of the strap iron of required length to hold the bottom angle iron and the iron band of the gunwale the proper distance apart. This done, hold a plate of iron against the angle iron at the bottom and against the inner side of the iron band of the gunwale. Mark off the outlines required for as large a pattern as it may be desired to make any single piece of the sides. Allow for all seams or laps. On the outline of the sides above the gunwale allow 1 inch of iron. This is

to be turned over inner ½-inch strip when this strip is placed in position. The bottom of the boat is made the same in shape as the outlines of the bottom angle iron demand, and cut out after the iron required for a double seam has been allowed. For a skiff of the dimensions given by the drawings in Fig. 1 the sides may be made of No. 26 gauge galvanized iron. Use 24 gauge iron for the bottom, using if possible a single piece. The sides and bottom may be joined together by a double seam. This will be as safe and as strong a joint in this position as a riveted joint would be, owing to the stiffness and protection provided for it by the bottom angle iron of the boat. Any cross seams occurring on the sides may be riveted. After all the parts have been made ready put the sides and bottom together, then solder and thoroughly soak each seam. For additional strength fit over each end, on the outside of the end joints where the sides come together, pieces of heavy galvanized sheet iron, as shown by the side view in Fig. 1. After these plates are placed in the positions desired close rivet them, as shown, then solder and soak the joints and rivets in a thorough manner. Now place the bottom angle iron frame (to which the four supports of the middle seat have been bolted) in position. The bottom frame must, as a matter of course, fit snug against the sides and the bottom of the shell.

If the frame at any point does not fit just right this fault must be remedied. This done, rivet the frame to the bottom and sides, have each rivet finish flush on the outside of the boat; then thoroughly solder and soak each rivet from the outside; then place, fit and rivet the braces X′ and X″ in their proper positions, as demanded, also the supports for the two end seats from the braces X′ and X″ toward the ends A and B of the boat. This done, solder the rivets on the outside of the shell.

Now prepare the wooden bulkhead J I for the air chamber. This should fit snug against the brace X′ and against the sides and bottom of the boat.

Fasten the bulkhead to the brace by short screws; then cover the inside parts of the sides, bottom and the bulkhead of the air chamber with a heavy coat of good paint. This done, cover the bulkhead J I on the outside of the air chamber with galvanized iron, and also the top from B to the bulkhead. Fasten these plates to the sides by riveting them and then solder and thoroughly soak each joint, &c., so that the air chamber will be perfectly air tight. The brace X may then be placed in position and the two end seats of the boat prepared, fitted and bolted in place. In the plan view, Fig. 1, but one half of each of the two end seats is shown in position by the shaded parts of the drawing. The other half of each seat has been left off to show the construction of the parts underneath the seats. The end seats may be made of some suitable hard wood, ⅞ inch in thickness. For the center seat use ⅞-inch or 1-inch stuff. This seat may also be placed in position and fitted in the manner demanded by the drawings, Figs. 1 and 5. This done, proceed to place the iron bands of the gunwale and also the two wood strips for the inner bands in position. As the sheer of this boat is but 4 inches, the 2-inch by ½-inch oak strips will readily bend to the regular curve without any previous preparation or steaming. The iron of the sides, as previously described, will project 1 inch above the strips and bands of the gunwale, after these have been fitted and bolted in the positions required. After this has been done turn the 1-inch projecting edge down and over the ½-inch inner strip. Do this neatly. Then nail the edge projecting down on the inner side with short wrought nails, spaced about 1 inch apart. Finish these edges as smoothly as possible.

The fittings, such as oars and special oar locks, required can be procured from any jobbing house handling boat hardware. Whatever style may be selected can readily be attached to the proper positions on the bands of the gunwale. Fig. 7 shows one method of fastening the fitting for an oarlock. To cover the bottom of the skiff use any desirable hard wood. Strips ½ inch thick by 3 inches wide will make a neat grating. Make the grating for the entire bottom of the boat in one piece by fastening the strips running lengthwise of the boat together with three cross pieces, one at each end and one in the middle under the center seat of the boat. So the center seat can be removed, the grating when made can readily be placed in position in the bottom of the boat. After this is in place fasten two strips on the grating at any suitable distance from the middle seat. These strips are to serve as foot rests for the person rowing the boat. After the entire iron and wood work about the skiff is finished, apply two coats of good paint to every part of the surface of the iron. The wood work can either be painted or finished in oil or varnished as desired by the builder.

Glass curtains, observes *Inventions* of London, are a novelty in art industry for house furnishings. They are in colored glass, and have the effect, when closed, of stained glass. They consist of a series of little squares of colored glass, each set in a small zinc frame, the squares being attached to each other at the four corners by little S-shaped hooks. We are told that they can be as easily taken down and moved as any other curtains, and, in case of changing from one size of window to another, can easily be enlarged or decreased in size by the addition or subtration of a certain number of squares. They are also easily cleaned, and one of their particular attractions is said to be cheapness. They are now being shown at the Palais Royal, Paris.

Propagation of Sanitary Knowledge.

In spite of all that is claimed for them, Americans have not as yet a complete monopoly in progressive ideas, and there are often valuable hints to be gleaned from the procedure of foreign municipal and other public bodies, of which we might with good advantage avail ourselves. In the matter of sanitation, for instance, there is much to be picked up. A news item in a recent number of a Scotch sanitary journal refers to a system which has been adapted with great success in a small Scottish county, and which appears to have been much appreciated by the public. Instruction in the principles of domestic and city sanitation, given in such a way as to reach the popular understanding, has been for some time given by the sanitary inspector of the county of Wigtownshire, Scotland, a small and somewhat unimportant county, which has hitherto never been looked upon as a leader in scientific progress. The inspector has been delivering a course of free lectures of a popular character at different centers throughout the county. These lectures, which were illustrated by lime-light pictures, dealt with such subjects as the practical principles of sanitation, cleanliness, sanitary duties of householders, the worth of fresh air and other matters of everyday importance. The importance in homes of good lighting, efficient plumbing, healthy methods of heating, &c., was prominently brought forward, and we learn that great interest was excited, which has borne practical fruit throughout Wigtownshire. This is just a sample of what might be done in this line to enlighten the general public everywhere on the important question of domestic sanitation.

Bell Founding.

The art of bell founding, observes the *Gentleman's Magazine*, is undoubtedly of great antiquity. The Saxons are known to have used bells in their churches, although probably small ones, for the venerable Bede, writing at the end of the seventh century, alludes to them in terms which seem to show that they were not unfamiliar things. The towers of the Saxon period have belfries of considerable dimensions in most cases; and at Crowland Abbey, in South Lincolnshire, there was a famous peal of seven bells many years before the Norman Conquest. The monks at that time, and for long after, were the chief practitioners of the art of bell founding, which, indeed, is one of the many things those well abused men have handed down to us.

Their bells were rarely without inscriptions, often in very bad Latin, containing, perhaps, some obscure joke, the point of which is quite lost. More often they were of a religious nature, sometimes, we fear, not unmixed with a dash of superstition, as when the bell declares that its sounds drive away the demons of the air who caused pestilence and famine, lightning and thunderstorms. As a rule, unfortunately, they put no dates on their bells—a defect which has been in some measure overcome by the researches of many enthusiastic campanologists, but which is likely to keep the early history of bells shrouded in darkness for a long time to come.

Fair Notes.

In the southeast corner of the Anthropological Building at the World's Fair are a few interesting sanitary and hygienic exhibits that are well worth visiting. It might at first thought seem out of place to show apparatus of this sort among gymnasium outfits, model prisons, diagrams of the distribution and kinds of criminals and various devices relating to the science of penology, but when it is considered how large an influence good health has in lessening crime the location of these exhibits will not appear unreasonable. There are some foreign exhibits relating to quarantine work that more especially interest the medical profession, but what our readers care most about are the following:

THE FULLER & WARREN WARMING COMPANY,

Chicago, show a No. 950 Fuller & Warren horizontal school furnace set in position in the way it would be placed in the cellar of a building. The furnace is built of cast iron sections of circular form, with corrugated exterior and bent flues piercing the sections from the side to give large heating surface. The furnace is made in two sizes, and the capacity can be altered by adding sections at the end. The grate is 2 feet 3 inches by 3 feet 3 inches, with rocking bars, and has cast-iron sectional ventilated lining. These furnaces are part of the heating and ventilating system of the Fuller & Warren Company, the ventilating feature being shown by a vertical shaft operated by the Holbrook syphon system. In the Fuller & Warren plan the heating and ventilating systems are distinct and separate, which feature they refer to as overcoming entirely the danger of offensive odors reaching the school room.

BROWN & SHARPE MFG. COMPANY,

Providence, R. I., have examples of sanitary closets on exhibition. The closets intended especially for shops, mills and factories, are iron hoppers for double closet, falling toward the center, where there is a device for periodical discharge of the contents. There is also an iron pipe about the top serving as a flush rim.

J. A. BOWDEN & CO.,

Detroit, Mich., show the Bowden single valve filter and illustrate its efficiency with jars of water "before and after using."

THE PASTEUR-CHAMBERLAND FILTER COMPANY,

Dayton, Ohio, have a pretty display of nickeled filters, and also glass apparatus showing the operation of the device. This firm, we understand, now control the filter in the United States, having bought the right from Dr. Pasteur.

W. D. CUMMINGS FILTER COMPANY,

Philadelphia, have several filters in operation. These filters use bone black as a purifying agent, besides filtering material for removing solid impurities from the water.

THE M'CONNELL FILTER COMPANY,

Buffalo, N. Y., exhibit in a blue-lined booth various styles of the McConnell Polar Electric Germ Proof filter. The special feature of this filter is the use of one large tube of a dense clay giving an extended filtering surface. The tubes are adapted to both gravity and pressure filtration. Part of the exhibit consists of coolers in connection with these filters. A notable feature of the filters is the cleaning arrangement which permits the easy removal of dirt from the clay cylinder.

THE BOSTON FILTER COMPANY,

Chelsea, Mass., exhibit the Boston Water Purifier, a filter for faucets and for gravity use. The filtering material is an unglazed porcelain tube closed at one end, the water passing from the outside inward, leaving all suspended dirt and organic matter on the outside of the tube. The tubes are easily removable and are cleaned with sand and a brush. By filling the tube with animal charcoal all organic discoloration can be removed.

ALBERENE STONE COMPANY,

New York, have in place an interesting display of laundry tubs, sinks, griddles, foot warmers, &c. The material is claimed to be absolutely non-porous and is therefore a sanitary article of high value. It is said to be acid resisting, and with a hard, fine surface is easily kept clean.

THE PERFECTION CLEAN OUT COMPANY,

Haverhill, Mass., show vertical lines of pipe made up of T's, Y's and straight lengths and all fitted with perfection clean outs. This device, with which our readers are familiar, offers a simple means of getting gears to a pipe at any point where there is danger of stoppage.

NORTON BROS.,

Chicago, show examples of the Norton hermetic seal noisless sanitary fixture, a water closet for which special features are claimed in respect to its seal, which is a bronze valve controlling the inlet of water and also the outlet of sewer. The closet is operated by a lever handle at the side of the seat.

THE AKRON, CANTON STONEWARE AGENCY,

Chicago, have a booth containing a number of combined filters and water coolers, some of the latter being tastefully decorated. The filter proper is a disk of natural stone, through which the water percolates, leaving the sediment on the top side. The disks can be easily removed and cleaned. A pressure filter is also shown, consisting of a nickel-plated shell holding a cylinder of stoneware through which the water is passed.

W. E. BEVERIDGE,

Baltimore, Md., displays the Beveridge automatic cooker in a large variety of sizes. The cookers are arranged about three sides of an alcove and make an attractive showing.

WILMOT CASTLE COMPANY,

Rochester, N. Y., have an interesting collection of cooking apparatus. The Arnold steam cooker consists of a water bottom in which the steam is generated rising into a cylindrical chamber above it in which are the receptacles for food. The apparatus is very compact and is said to be especially useful in connection with gas and gasoline stoves, though it is also useful with coal stoves. The Arnold Steam sterilizer is also a part of this exhibit, which is in charge of N. H. Peterson.

UNITED INDURATED FIBER COMPANY,

Eastern agents, Cordley & Hayes, New York, and Western agents, Indurated Fiber Ware Company, Chicago. The display of this company is in the Forestry Building and consists of a pavilion built up largely of indurated fiber goods. The pillars supporting the roof are made up of bowls, pails, basins and tubs, while the electric lights between them are shaded in funnels of the same material. All about the display the eye is arrested by an article of indurated fiber put to some such extraordinary use. Besides the make up of the pavilion, a large variety of other articles are displayed about the counters. A notable article among the variety of goods is a bathtub made by the Oswego Indurated Fiber Company. Altogether about 100 different articles are exhibited, which show the wide application of this material. The exhibit is in charge of Homer Drake.

Cost of Living in European Cities.

A commercial return has recently been issued in England which gives some interesting particulars as to the comparative price of certain staple articles of food in various cities of Europe. The cities selected are Paris, Lille, Frankfort-on-the-Main, Hamburg, Berlin, Vienna, Buda-Pesth, Prague, Rome, Florence and Brussels, and the figures given show the average retail price per pound, avoirdupois, of articles of domestic consumption, medium qualities, such as would be obtained by working people. The prices of prime beef varied very much. In Prague it could be obtained for 14 5 cents a pound, in Vienna for 16 cents, in Rome and Buda-Pesth for 18 cents, while in Paris the price fluctuated between 25 cents and 35 cents, and in Lille as much as 37.5 cents had to be paid. Flour ranged from 2.40 cents in Buda-Pesta to 5 cents in Paris, Frankfort and Florence. It is curious to notice that, while in Lille flour could be purchased for 4 75 cents a pound, and white household bread cost 3.40 cents, in Berlin this was exactly reversed, bread costing 4 75 cents a pound, and flour being 1.10 cents cheaper. Potatoes were under 2 cents a pound in all cities except Hamburg. Rice ranged from 3.40 cents (in Brussels) to 10 cents, sugar, "good white lump, cracked or sawed," from 8 cents to 15.50 cents (in Rome and Florence); and coffee, Brazil or plantation, roasted and ground without chicory or other coffee substitute, from 35.50 cents in Berlin to 62 cents in Paris. In Brussels, coffee from the Dutch colonies can be obtained for 30 cents a pound.

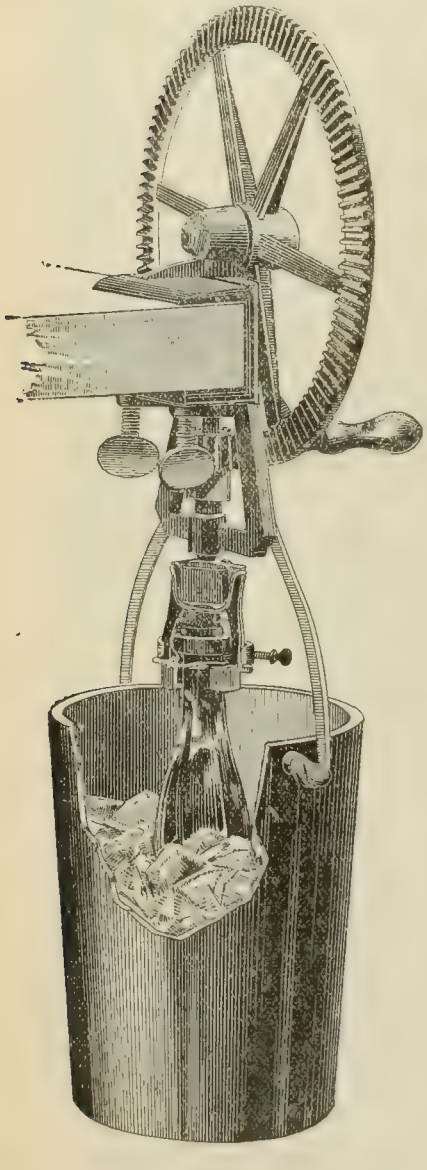
In connection with this subject it may be mentioned that Dr. Ogle, an English statistician, has lately stated, as the result of investigations made by him in London, that he had ascertained the average income of 21,443 workingmen in full employment, representing with their families 97,784 persons, to be $6.28 a week; or an average of $1.37 for the maintenance of each member of a family. The rent expenses averaged $1.48 a week, or 23½ per cent. of the total receipts.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until July 25, for all the labor and materials required to put in place complete the cast iron and Z-bar columns, steel and iron floor, ceiling and roof construction, ceiling light, skylight roof, dormers, &c., for the United States Post Office Building at Worcester, Mass., in accordance with the drawings and specification, copies of which may be had from the Supervising Architect at Washington, or the Superintendent at Worcester, Mass.

THE RETAIL STORE.

Wine or Beverage Cooler.

Cobin Mfg. Company, 107 Chambers street, New York, are introducing a wine cooler, as here shown. This apparatus is designed to freeze or frappé a bottle of wine or other beverage in from three to five minutes, and is intended to obviate the necessity of keeping various bottles in the refrigerator. It also enables a host to meet an emergency quickly. The bottle may be cooled in the ordinary fiber or other



Wine or Beverage Cooler.

bucket with the usual ice and salt mixture. With each machine is included a perforated zinc shell, which can be slipped over the bottle in the ice, permitting the bottle to be drawn from and replaced in the cooler instantly. The machine is galvanized to prevent rust, is 20 inches long, the large wheel being 12 inches in diameter. To make it noiseless, the small gear is of rawhide, while the clamps catching the neck of the bottle are lined with the same material. In commercial shape, the apparatus, bucket and zinc shell are put up complete in a crate in shipping order.

The Go-Bang Rat Trap.

Waddel Wooden Ware Works, Greenfield, Ohio, are putting this article on the market, an illustration of which is

The Go-Bang Rat Trap.

given herewith. This trap can be set automatically by the hand or foot. Its construction is such, it is stated, as to render its action unerring, the simplicity being also referred to as reducing the cost of manufacture to a minimum.

Royal Coffee Pot.

M. Stransky & Co., 27 Murray street, New York, are offering the above goods, as illustrated herewith. They are fur

Royal Coffee Pot.

nished in assorted colors, cameo, inlaid and garnet. The features of the pot are the hinge and the manner in which the wooden handle is fastened to the body of the pot. Two rivets, on which a thread is cut, pass through the body of the pot at the back, near the seam, and are riveted on the inside of the pot before the coating is put on the metal. The handle is fastened to metallic pieces, which, in turn, are secured to the pot by caps screwed on to the threads of the rivets. The hinge is fastened to the upper metallic piece. This arrangement is referred to as preventing the handles from getting hot or coming off. Tea pots are provided with the wooden handle and hinge the same as the coffee pots. The covers of both lines of goods are nickel plated.

Export Notes.

A New York exporting house of much experience, handling American products, has recently shipped an order for Band Iron aggregating 1500 bundles and weighing 67,000 pounds. They also report good orders for Merchant and Bar Iron, square, round, angles and various shapes of miscellaneous sizes and dimensions in addition to a shipment of three carloads of Boiler Plate, not long since. Their orders have run in 50 to 150 bundle lots of a size or kind, and so far, although competing directly with English manufacturers, have not had a complaint as to quality. Out of 250 letters sent to foreign clients in this trade all but 10 per cent. responded in some form or other, showing a desire to trade here if their wants can be met.

We know of an instance where a first order for a case of sheet metal to be used in the arts abroad, amounting to but $32, was received and properly executed. On its arrival out, care having been taken to follow directions, &c., it was quickly followed by a second order of 40 cases of the same goods, of a total value of $900. This is not only another instance of the wisdom of properly filling an order in all its details, without regard to the value of the invoice, but is evidence of a practical character that our neighbors in the West Indies, Central and South America can be induced to largely increase their purchases with us, if we will but note their explicit commands and follow directions.

An incident occurred recently which indicates somewhat the extent of progress trade is making with commercial houses in Spanish America affected by some of the reciprocity treaties now in operation. A buyer came to this city with memoranda for a line of iron of various kinds, amounting in all to 20 carloads. After much inquiry and the receipt of numerous quotations the orders were left here, whereas formerly they had been executed in England and on the continent. This is referred to by those interested as showing that mill men are coming to see the value of securing these orders, and are now working in harmony with those able from many years of experience to influence such orders.

COBIN MFG. COMPANY, 107 Chambers street, N. Y., are introducing a Refrigerator Shelf, a patent for which has been applied for. It is a combination of steel strips, tubes and rods in a frame, which can be of any size or shape. It is galvanized after it is made. Emphasis is laid on the fact that there are no cracks, crevices or holes into which substances of any kind can accumulate and decompose, and that it can be quickly cleaned.

STOVE TRADE NOTES.

The Future of the Hot-Air Furnace.

By A. W. Glessner,

President of the Excelsior Steel Furnace Company.

A NEW FIELD FOR FURNACES.

In a former article reference was made to the fact that in Philadelphia and elsewhere furnaces were being placed in workingmen's homes, and it is difficult to overestimate the importance of this movement, for it opens up a new and wide field for the hot-air furnace. The effect will be to take the hot-air furnace from the list of luxuries and place it where it properly belongs, among the necessities of the modern home. The fact is that no intelligent man, be he clerk, mechanic or laborer, can afford in building a home to attempt to heat it with stoves if he has any idea of economy. Building to-day has reached a point where the cost is computed upon the cubical contents of the same as compared with the available rentable space in square feet of floor, and 'twere folly to build a house and then sacrifice in each room from one-eighth to one-tenth of the floor space by the introduction of a stove. A room 10 x 12 feet, heated by a furnace, is more available than one 12 x 14 feet, heated by a stove, as a stove cannot be tucked away in a corner nor up against the walls, and neither can any piece of furniture be placed in close proximity, so that a large proportion of the best part of the room must be given up to the stove. Furthermore, if all rooms and halls are to be heated by stoves, then more than one chimney must be provided, taking up additional room and requiring additional capital. In this climate the Chicago *Tribune* has stated that there are but two months in the year when artificial heat is not required, and in all places north of the Mason and Dixon line artificial heat must be had during portions of fully eight months out of the 12. Hence, it follows that the man who heats by stoves must yield during two-thirds of the year very valuable space to his heaters, and must, accordingly, provide rooms of greater size; and if the additional cost was estimated it would provide the fuel for heating the building for a term of years, to say nothing of the saving of the interest on the additional cost.

The introduction of the hot-air furnace into the workingman's home marks an important economic fact, which is that the time has arrived when a hot-air furnace can be installed in a house of moderate size for less money than can stoves of sufficient capacity to heat it, and this can be easily demonstrated. Recently a contractor in Philadelphia built a large number of houses of small size, and, as is customary in that city, a hot-air furnace and brick-set range were required in each house. Bids were invited and a contract was let for this work at a price for the two articles duly installed actually less than I have known a gentleman in an Illinois town to pay for a heater of large size set up in his parlor, and the figures in the former case, while close, admitted of a margin, though a small one. The castings of the furnaces were supplied by the manufacturers, and the steel work was mounted by the heating contractor. What gauge of steel was used I do not know.

(To be continued.)

Peninsular Stove Company.

We are indebted to the Peninsular Stove Company, Detroit, Mich., for an attractively printed catalogue within the covers of which attention is called to the extensive line of stoves, furnaces, cast iron and wrought steel ranges which they manufacture. The work is issued in the form which has proved so popular with the trade and which renders reference to the various lines of goods shown convenient and easy. The Peninsular wrought steel range is the first candidate for consideration, this being a construction for which the makers urge many claims. The fire box and flues are said to be so disposed that the products of combustion are directed in an even and thorough manner over all the plates, making it a quick, powerful and efficient baker. In the construction of this range the company have aimed not only to produce the largest assortment, but to make it the finest in finish and most complete in detail of any line on the market. Tables are presented giving the oven dimensions, cooking surface and other particulars concerning the various sizes in which the stove is made, while a price-list shows the figures at which the goods can be obtained. The cast-iron ranges occupy something over 80 pages of the catalogue and are under names in which the word "Peninsular" is a prominent factor. The same may be said with regard to the cook stoves, which are illustrated and described in the 40 pages which follow. The heaters are represented with the Regal Peninsular in the place of honor. This stove has a large radiating surface, embodies the modern improvements and is so constructed in its various parts as to prove a powerful heater in operation. It is shown in several varieties, followed by the Royal Peninsular, which is similar in its make-up to the one just described, but it is somewhat less in price. The Radiant Peninsular is another handsome parlor stove, as is also the World's Leader, a surface burning construction adapted for hard coal, coke or natural gas. The Oak Peninsular is shown in several varieties, following which we find the Franklin Peninsular, a richly treated stove; Empire Cannon, the Crystal Peninsular, a handsome wood base heater; the Diamond Peninsular, a member of the same class; the King, a neat box stove, and a line of hot-air furnaces, one of which is intended for burning wood only. Several pages are given up to a price-list, dimensions and capacities of Peninsular furnaces, following which are price-lists of stove hollow ware, mica, fire-brick linings, sundries and a general index.

The Thomas, Roberts, Stevenson Company

of Philadelphia have issued to the trade a catalogue of 222 pages, covering their line of stoves, ranges and furnaces. The prefatory address to the trade appears in English, German and Spanish. Among the new goods mentioned in the book are the Ideal Fortune, a six-hole range, with right or left hand oven or fire, wrought-steel oven, sheet flues and slide in bottom of oven, to allow of easy examination or withdrawal of contents; a plate rack, with gas burners, on which a patent is pending, for use as a warming shelf or for burning gas on top surface of range; the Colonial Fortune six-hole range, possessing the same general features as the Ideal, but designed particularly for the building trades, and the Hecla Fortune open grate or fire-place Heater, with round or square frame, designed to heat the air entering in front through the skirt or base and discharge it into the room in which the heater is set, or by means of a damper to allow of its ascent to an upper room. The other articles illustrated and described in the book are the well-known New Altoona, New Broadway, New Happy Choice, Extra Fortune, Ivy Fortune, New Fortune, New Finest, New Champion, Windsor, Superior, Crescent, Pearl, Grand Times, The Times, Good Times, Harvest Home, Virginian Girl, Zeb Vance, Georgia Queen, Southern Baker, Southern Queen, Iron City, Southern Gem, Jumbo, Active Fortune, West Side, Regal Fortune, Modern Fortune, French Fortune, Home Fortune, Gem Fortune, Fountain, Star Fortune, Phœnix and Atlas ranges; their line of furnaces comprising the Challenge Syphon, Star Syphon, Fulton, Popular Finest, Popular Fortune, Phœnix Portable and the Iron Clad air-tight wrought-iron furnace, with new front and triplex grate. Heating stoves covering the Sterling Fortune, a new base burner and double heater (described in a recent issue), Vesuvius, The Leader, Haverford, Violet, Banner, Daisy, Daisy Egg, Pavilion, Electric Franklin, Franklin Pride, New Favorite, Garnet, Bon Bon, Eureka, and numerous Laundry and other heating stoves for all purposes. Especial features of the catalogue are a chapter on "Setting and operating Active Fortune Ranges," which anticipates all the difficulties likely to occur in situating the ranges, and clearly illustrates the right way and wrong way of connecting the boilers with the water backs; outline cuts of the Active Fortune, and Regal ranges, and the Challenge Syphon furnace, with dimensions; an illustrated treatise on ventilating canopies, and a quantity of information useful to the trade. The book is well printed on good paper and bound in a stiff buff paper cover with the name and address of the company embossed on the fronts. The Gauze door ranges and stoves made by the company under the Giles F. Filley patents are described in a separate catalogue issued by the company.

The Joliet Stove Works

of Joliet, Ill., have just issued from the press their thirteenth annual catalogue, which is a neat volume of 36 pages, bound in terra cotta colored paper covers. In offering this volume to the trade the company direct attention to a few facts which are likely to prove interesting. They state that from their infancy in 1870, when only a few men were employed, their business has expanded, until to-day 200 skilled workmen are employed in manufacturing cook stoves and heaters. They employ nothing but the highest grades of pig iron in the construction of their goods, which have established a gratifying reputation in the trade. The company have recently added a new line of Moore's ranges for both hard and soft coal, and have embodied some new features in Moore's air tight heater. The ranges which are considered include Moore's Perfection, made with six boiler holes, duplex grate, large square oven, draw out hearth, extra large broiler door and rich ornamentation; Moore's Fidelity, a six-hole range for burning soft coal or wood, made in a number of styles and sizes; the Fidelity, a medium-priced range of attractive appearance; the Fidelity cook, having large oven and fire box, especially adapted for burning soft coal, and the Fidelity four-hole wood cook. The leading place among the heaters is given to Moore's air-tight parlor stove, which is richly ornamented with nickel and art tile, and embodies features of construction which render it powerful in operation. The Fidelity Todd for wood and the Joliet cannon stove are also illustrated and described. Accompanying the catalogue is a little pamphlet entitled "The Reasons Why." Glancing over its pages we find the matter to consist of a series of testimonial letters, telling of the satisfaction which Moore's air-tight heater has given to those who have practically demonstrated its merits.

The Co-Operative Foundry Company

of Rochester, N. Y., have issued their twenty-seventh annual catalogue of the Red Cross line of parlor and cook stoves, ranges, &c. The volume measures 5½ x 7¾ inches, consists of 120 pages of profusely illustrated text, and is bound in flexible covers, carrying an embossed side title in old gold and green. The design includes the name and address of the company, as well a sa *fac-simile* of their trademark. The opening pages are devoted to the line of Red Cross ranges, which are shown in great variety. This line embodies among its features a draw-out oven rack, which permits the contents of the oven to be readily inspected; large ovens, perfection grate and attractive ornamentation. In addition to the Red Cross we notice the Monroe, the Model Red Cross, the Iroquois Chief, the Red Cross Herald, the Favorite and the Red Cross Talisman. Under such names as the Magic Red Cross, the Maple Leaf, the Red Cross Champion and the Red Cross Banner the company offer an interesting assortment of cook stoves adapted for burning coal or wood and for wood only. The leading place among the heaters is given to the Red Cross square parlor stove for hard coal. This is well known to the trade, having been extensively introduced, and is this season offered in the same graceful outlines and effective decoration which has characterized it in the past. The Royal Red Cross is a neat square parlor for hard coal embodying the latest features and is shown in general and sectional views. The Brilliant Red Cross for burning natural gas, the Black Prince, an all-cast cannon; the Red Cross oak, Sylvan Red Cross cottage parlor and the Sunflower box are some of the other goods illustrated and described. The closing pages of the catalogue are given up to hot air furnaces and a miscellaneous list of hollow ware, price list of stove and range linings, North Carolina mica, sundries, stove platforms and a general index.

The Chicago Stove Works.

We are indebted to the Chicago Stove Works of Chicago, Ill., for a copy of their annual stove catalogue, printed in good style upon white paper and bound in ornamental paper covers. The side titles are printed in old gold and a delicate shade of green upon a black groundwork, and give to the volume a very attractive appearance. The early pages of the volume carry a general view of the works of the company at Chicago, and also of the plant of the Bussey & McLeod Stove Company, Troy, N. Y., who manufacture Gold Coin stoves in the East. The goods shown include a varied assortment of cook stoves, ranges and heaters, made under the generic name Gold Coin. The features embodied are of the modern type, while the ornamentation is of a character to please the eye. The goods have established for themselves a wide reputation in the trade and are known over an extended territory. The Gold Coin ranges occupy nearly 75 pages of the volume, among the goods being several new patterns for this season. The cook stoves are considered in the following 30 pages, after which we find an interesting assortment of heaters. These are presented under such names as the Gold Coin square wood base-heater; the Gold Coin Ventiduct wood parlor; the Gold Coin Ventiduct oak; the Gold Medal Todd; the Ajax box for wood only; the Gold Coin Ventiduct base burner with hot air flues, a stove which has been improved for the season of 1893; the Gold Coin base burner, an entirely new heater this season; the Gold Coin Ventiduct surface burner, and an interesting assortment of Franklin, Cylinder, Cottage Parlor, Globe, Cannon and laundry stoves. The catalogue considered as a whole is well arranged and is likely to find a place among the literature of the dealer into whose hands a copy may come.

The Michigan Stove Company.

Among the handsome trade catalogues which have come to hand the present season, that issued by the Michigan Stove Company takes a high rank. Its general make-up gives evidence of a careful attention to details and due consideration of the requirements of the stove dealer. The matter contained within the stiff board covers of the volume is of such a nature as to prove both interesting and valuable to those for whom it is intended, while the mechanical execution entitles it to a prominent place in the dealer's library of trade literature. The volume is made up of 176 pages, the body of each of which is of a delicate shade of chocolate, relieved by an ornamental border in a lighter color. The printing is in pure black, forming with the paper of which the volume is composed, a striking contrast. The corners of the pages are rounded, thus adding to the general effect, while the covers are ornamented in silver and black upon a groundwork of terra cotta. A commendable feature of the catalogue is a back title, consisting of the words "Garland Stoves and Ranges, 1893-94." By this means the volume may be readily identified by the dealer, even when filed away with other trade literature. The opening pages are given up to a list of the officers and directors of the company, a general view of the Western headquarters in Chicago, a statement of terms, a telegraphic code for use in ordering goods by wire, an illustrated description of the Garland Aerated Oven, the success of which has been pronounced, and some general remarks on the subject of advertising. As our readers are well aware, the goods of the company are made under the name "Garland," which word is used in combination with others to designate different varieties. The ranges occupy nearly 65 pages of the catalogue and are shown in great assortment. The ornamentation is of a high order, producing rich and beautiful effects, while the constructive features are such as to give the goods a wide reputation. Cook stoves follow the ranges, after which we find the Garland line of heaters. Many of these goods have been improved and redressed for the season of 1893, while a number of new patterns have been added. The constructive features are of the latest type, the ornamentation is rich and handsome and the varieties offered sufficient to meet all requirements of the trade. The leading place is given to the Art Garland for hard coal or coke, following which is the Peerless Garland, the Alpine Garland, the Novel Garland, Acme Garland, the Syphon Oak Garland, the Horizontal Garland, the Oak Pennant and the Hickory Pennant. A feature of the catalogue which cannot fail to be appreciated by intelligent dealers everywhere, is found in the closing pages, which give sectional views of cook stoves, ranges and heaters, with all the parts numbered, each number referring to an explanatory table. This permits the dealer ordering repairs to designate the parts by their correct names and thus avoid many of the annoyances and mistakes which are so common to this branch of the business. A price-list of brick linings, mica and sundries, together with an index for the telegraphic code words and a general index complete the catalogue.

ODD PLATES.

MERRILL B. MILLS, treasurer of the Michigan Stove Company, is the owner of a beautiful steam yacht, "Grace," which is now cruising in Lake Michigan in the vicinity of Chicago. On the 15th inst. the employees of the Chicago branch of the Michigan Stove Company were favored with an invitation from Mr. Mills to enjoy the hospitalities of the "Grace" in a cruise on the lake, occupying the afternoon. The invitation was conveyed by means of a very dainty card, beautifully printed and couched in formal, but graceful language as befitted the occasion.

THE FOX FURNACE COMPANY of Cleveland, Ohio, have brought out a hot-air heater which is claimed to embody the latest improvements, and which is so constructed as to give satisfactory results in operation. We understand that price-lists will be furnished to those who may apply.

J. D. MARVIN, representing the interests of the Fuller & Warren Company, Troy, N. Y., started this week on his tour among the stove trade of Long Island. After covering that territory he intends to call on dealers in Connecticut and Massachusetts.

THE LATEST ADVERTISING NOVELTY issued by the Barstow Stove Company, Providence, R. I., is a folded card, circular in shape, and intended to represent a small globe of the world. Opening the folder we find an announcement to the effect that the company could not get sufficient space at the Chicago Fair for a satisfactory display of their goods, and they therefore decided to make no exhibit. They inform the reader, however, that he may look the fair over, or even the world, for that matter, and he will find no better line of furnaces, ranges or parlor stoves than the Bay State line.

THERE is a restaurant in Paris where all the cooking is done by electricity.

THE AMERICAN TUBING & WEBBING COMPANY have, since the big fire in Providence, R.I, on May 21, of the present year, by which a portion of their works were destroyed, established a model tubing factory, equipped with the latest improvements in the way of machinery and appliances. The company manufacture flexible gas-tight tubing, oil stove wicks, silk and cotton elastic webs, and state that they are now better prepared than ever before to promptly fill all orders with which they may be intrusted. The company control Caldwell's patents, and the statement is made that all buyers of flexible gas conducting tubing, with the large molded rubber end and nickel or brass ferrule, are liable to prosecution, as the same are alleged to be infringements on the Caldwell patents.

WE HAVE RECEIVED from the Michigan Stove Company during the week some of the advertising novelties which they are distributing. Among these are a Japanese fan, which bears on one side a copy of the company's trademark with appropriate inscriptions, also a piece of sheet music entitled "Afterwards," the words composed by Mary Mark Lemon and the music by John W. Mullin. The Michigan Stove Company are particularly active just now in calling the attention of the trade to their goods by means of these clever devices.

THE ART STOVE COMPANY of Detroit, Mich., have just completed a full line of new parlor stoves known under the name Laurel. The vertical flue construction has an attachment whereby it may be converted into a base burner, and the manufacturers state that a series of tests made with this stove developed something decidedly interesting in the way of results obtained. The heater gives promise of being a good seller, and the design ranks well with the new stoves now on the market.

THE STUART-PETERSON COMPANY, who, in May last, removed their works from Philadelphia, Pa., to Burlington, N. J., commenced work on orders within six weeks of leaving their old quarters. They are already finding their foundry too small for their largely increased business and will, in the fall, extend their buildings some 60 feet. They have also in contemplation the erection of a dry room for the storage of polished stock. This is a much needed department, owing to the liability of polished iron to rust when in the least exposed to atmospheric influences. The company are receiving bids for a wharf extension to be built this fall. When constructed it is proposed to fill it in with their own dumpage. The completion of the wharf will afford excellent facilities for water shipments. The company are furnishing employment for about 100 hands, but this number will have to be considerably augmented before long.

THE ECLIPSE STOVE WORKS of Mansfield, Ohio, resumed operations last week after a brief shut down for annual repairs, &c. We understand that the company are giving employment to a larger force than ever before.

ACCORDING TO THE LATEST ADVICES from Sioux City, Iowa, it is the intention to reorganize the stove works at Leeds and put the plant into active operation. A committee was recently appointed to secure the consent of the creditors to a plan of action, and it is stated that the members of it are meeting with gratifying success.

AT THE ANNUAL MEETING of the stockholders of the Somerset Stove Foundry Company, recently held in Somerset, Mass., John D. Flint was elected president for the ensuing year and William P. Hood, treasurer and general manager. The directors elected include John D. Flint, Hon. D. S. Stevens, Isaac T. Brownell, A. N. Lincoln, Alfred H. Hood and William P. Hood. The report presented at the meeting was very satisfactory, and after paying a dividend from the earnings of the past year of 6 per cent. a handsome surplus was left. In addition to their large line of ranges, which embrace the Harvest, Palace, Arion, Wyoming, Somerset, Grand and Grecian, the company are putting on the market an entirely new low-priced range called the Somerset Jewel. This stove embodies the improvements of first-class and higher-priced ranges and is expected to meet with a gratifying sale. The company are also making a full line of parlor air-tight stoves, and have remodeled the Superb, Arion and Vesta cook stoves. They employ only the best materials in their goods, as well as the highest skilled labor, the latter having been the former owners of the concern when it was known as the Somerset Co-operative Foundry Company.

BERGSTRON BROS & CO. of Neenah, Wis., send us a number of advertising blotters which they are distributing. These are neatly printed on one side with an illustration of some stove, its good points being also enumerated. The batch received covers the wood cottage stove Spark, the wood parlor stove Tacona, the Royal Oak, the New Elmhurst surface burner Nos. 14 to 18, and the New Elmhurst Nos. 20 to 22. An illuminated circular accompanies these blotters, giving points on the Royal line of oak stoves made by the firm. A decidedly convincing list of the advantages of this system is presented in the circular.

THE GOBEILLE PATTERN COMPANY, Cleveland, Ohio, are distributing among their friends in the trade copies of the official souvenir postal, on the back of which is a general view of the Manufactures and Liberal Arts Building at the Columbian Exposition, together with supplementary matter of an interesting character. On the lines intended for writing is the statement by the company that their shop is just as unlike all others as the postal card is different from the ordinary. In conclusion, the company say: "We make patterns better and cheaper than any other shop."

THE TROY OIL STOVE COMPANY of Troy, N. Y., have about ready for the trade a new oil heater, which they claim will be the "best and cheapest on the market." Its constructive features will be such that it may be used for both heating and cooking purposes, and as it will have a flat wick with central draft no engineer will be required to run it.

J. D. HIESTAND, manager of the Philadelphia office of the Keeley Stove Campany of Columbia, Pa., has just returned from a visit to the World's Fair, and is quite delighted with the Exposition. The Columbian line of stoves, ranges and furnaces will now have their merits extolled in a manner becoming the Columbian year and celebration.

KNOTT, HARKER & CO., Beaver Falls, Pa., have just moved their office and showrooms to a new two-story building 40 x 80 feet. The first floor will be used as a machine shop, which has windows for light under the work benches that run along one wall as well as above them. This will have a tendency to promote cleanliness and prevent the usual accumulation of odds and ends. The ceiling is very high and the windows are of a size to let in an abundance of light. On the second floor, which also has a very high ceiling, the offices occupy the front while the large space back is lighted by large windows some 6 feet above the floor. This space is divided into a number of smaller rooms where an elaborate display is made of mantels of marble, slate and wood, of grates, fenders, screens, fireplace linings, andirons, borders and summer pieces in plain, nickel and bronze finish, and a line of art tile that leaves little to be desired. These goods are the special feature of their business, though many castings are made in their foundry and considerable machine work is done for their customers. A large foundry and manufacturing plant right on the railroad adjoins the new building giving them excellent facilities for making, snowing and shipping a very handsome line of goods.

J. M. THATCHER, inventor of the well-known Thatcher furnace, died at Franklin, N. J., on July 19, while on a visit to his son, L. M. Thatcher, secretary of the Thatcher Furnace Company. Mr. Thatcher was 75 years of age. By his removal a familiar face will be missed from among the stove and furnace trade. He was, in fact, widely known throughout the United States, having been connected with these trades since his boyhood. Mr. Thatcher severed his connection with the Thatcher Furnace Company several years ago, and went to reside at Kansas City for the benefit of his health, which had become impaired by his busy life.

THE PETELER FURNACE COMPANY of Minneapolis, Minn., have recently issued from the press a neat little catalogue illustrating and describing their air-tube furnace. This is spoken of as scientifically correct in design and construction, and well adapted to the section of country in which it has been introduced. The device is shown in sectional view, and is described at some length in a way to render its features clearly understood. Attention is also invited to the company's hot water ventilating system, several points concerning which are fully set forth. A number of pages are devoted to what some of the manufacturers' customers say concerning their goods.

TRADE REPORT.

The Iron Market.

Stagnation characterizes the market along the whole line of Iron and Steel products in all sections of the country without exception. In some departments the condition of the industry is unprecedented. This is notably the case in the Lake Superior Ore district, which has never suffered as it is now doing. Other Ore districts, too, are feeling the pinch. The canceling of orders by customers has led to the closing down of mines in New York and New Jersey, and Lake Champlain Ores have been offered at exceptionally low prices.

In finished Iron and Steel the most telling event is the disagreement on the Western wages scale. At the present writing the outlook for an early adjustment does not look particularly brilliant. To the trade at large this will not be unwelcome news, since it cuts off some of the superabundant supply. The works directly affected have the choice of keeping closed down and losing trade, which really means very little, or of starting under the thumb of the Amalgamated Association.

Pig Iron.—The market in New York is lifeless, with occasional reports of concessions under fairly numerous special circumstances. Buyers are covering only immediate requirements, and these call for exceedingly quick delivery. We quote Northern brands at $14 50 @ $15 for No. 1; $13 75 @ $14.50 for No. 2; $12.25 @ $12.50 for Gray Forge, at tidewater. Southern Iron, same delivery, $13.75 @ $14 50 for No. 1; $12.50 @ $13.50 for No. 2; $12 @ $12.25 for No. 3; $12.25 @ $12.50 for No. 2 Soft, and $12.75 @ $13.25 for No. 1 Soft. Gray Forge remains $11.75 @ $12.50.

Not much business is being done in the Philadelphia market, but a steady tone is noticeable in quotations. The heavy decrease in production, coupled with light stocks, imparts confidence to holders of good brands; and, although it is hardly a time to talk higher prices, it is thought to be equally clear that prices will go no lower. Meanwhile business is being done at last quotations, which are as follows for Philadelphia and equivalent points, and from 20¢ to 30¢ less for Southern Irons at points accessible by water:

American Scotch, No. 1X...	$16.00	@	$16.50
American Scotch, No. 2X...	15.00	@	15.50

At Pittsburgh a few sales of Bessemer Pig have been made, which have forced the price of Bessemer in that market down to $13. The prospect of some business being done in Steel at an early date and the large falling off in production will, it is believed, favorably affect the market. Gray Forge and Foundry Irons are entirely neglected. Quotations are as follows:

No. 1 Foundry	13.50	@ 13.75	cash.
No. 2 Foundry	12.50	@ 12.75	"
Charcoal Foundry No. 1	17.00	@ 18 00	"
Charcoal Foundry No. 2	16.50	@ 17.00	"

Advices from Chicago report very little doing in Pig Iron in that market. Business is confined to customers who absolutely require Iron. Some inquiry, however, is stated to be coming from the country trade, who appear to be getting ready to buy. Very few furnaces are in operation in the vicinity, yet the supply of Pig Iron is considerably in excess of demand. There is absolutely no market for Lake Superior Charcoal Iron at present. The following quotations represent the regular asking prices, Chicago delivery, but they are subject to concessions according to circumstances:

Lake Superior Charcoal.....	$16.00	@	$16.25
Local Coke Foundry, No. 1...	13.50	@	14.00
Local Coke Foundry, No. 2...	12.75	@	13.00
Local Coke Foundry, No. 3...	12.50	@	12.75
Local Scotch.....	14.00	@	15.00
Ohio Strong Softeners.....	15.75	@	16.25
Southern Silvery, No. 1.		@	14.50
Southern Silvery, No. 2		@	14.00
Southern Coke, No. 2.....	12.75	@	13.00
Southern Coke, No. 3	12.25	@	12.50
Southern, No. 1, Soft.....	12.65	@	13.00
Southern, No. 2, Soft.....	12.25	@	12.50
Southern Gray Forge .. .	11.50	@	12.00
Tennessee Charcoal, No. 1....	16.50	@	17.00
Alabama Car Wheel.....		@	18.85
Coke Bessemer	14.50	@	15.00
Hocking Valley, No. 1	16 75	@	17.00
Jackson County Silvery.....	16.75	@	17.00

The Southern markets show no improvement in Pig Iron during the week, and yet there has been an increased volume of business, both for spot and forward delivery, the demand being mainly for single car lots of most kinds of Iron. There is scarcely any demand for Charcoal Iron, but Gray Forge Coke Iron is selling fairly well. Certain grades of Iron are scarce, and will become more so, and, with any easing in money, it is thought that prices will improve. Meanwhile, quotations are as follows:

Foundry.

Southern Coke, No. 1.	$13.00	@	$13.25
Southern Coke, No. 2.....	11.50	@	11.75
Southern Coke No. 3.....	11.00	@	11.25
Ohio Soft Stone Coal, No. 1....	16.00	@	16.25
Ohio Soft Stone Coal, No. 2....	15.00	@	15.25
Lake Superior Coke No. 1.....	15.00	@	15.25
Lake Superior Coke No. 2.....	14.00	@	14.25
Hanging Rock Charcoal, No. 1..	18.50	@	19.00
Hanging Rock Charcoal, No. 2..	17.50	@	18.00
Tennessee and Alabama Charcoal, No. 1.....	15.00	@	15.50
Tennessee and Alabama Charcoal, No. 2.....	14.00	@	14.50

It is expected that the improvements which the Baltimore & Ohio Railroad is making in West Virginia will develop large coal fields in that State.

Metal Market.

Pig Tin.—Speculative dealings during the past week involve a total of upward of 1000 tons, the greater portion on contracts for July and August delivery in settlement of old trades and against privileges. Purchases by distributors and consumers have been on a moderate scale. However, there is reason for the statement that, with proper allowance for the curtailment of consumption due to usual summer season dullness and extremely adverse financial conditions, to say nothing of the deliveries made since the 1st inst. on old contracts, stocks in first hands have been cut down considerably, making the statistical position much stronger than it was at the beginning of the month.

Copper.—The monetary situation still operates as a formidable obstruction in the way of improvement in the market for this metal. It curtails the home trade outlet and affects the foreign market perceptibly. As a popular quotation for Lake Superior Ingot, 10½¢ remains in force, but it is no secret that purchases can be made in some quarters at ⅛¢ @ ¼¢ ℔ lb less.

Pig Lead.—The market has weakened somewhat since the date of our last review and is at present in an uncertain shape, pending the solution of problems incidental to the silver agitation. A few sales have been made at 3.60¢ for early and 3.65¢ for more distant future shipment. Subsequently some lots were parted with at 3.55¢, and offerings at 3.60¢ were free enough to indicate that buyers have the upper hand to a great extent where deals involving more than single carloads are concerned.

Spelter.—There has been an uninterrupted downward turn in prices, with good Western brands selling in carload lots at from 4.15¢ down to 4¢, delivered, near future shipments, and fairly free offering at near the bottom figures at the close.

Antimony. — While not unusually large the arrivals have been sufficient to add to the accumulation here, and prices are easy in consequence. Ordinary jobbing lots out of store may be secured at 9¾¢ @ 9¾¢ for Hallett's, 10⅛¢ @ 10¼¢ for L X, and 10⅜¢ @ 10⅝¢ for Cookson's, on the spot.

Tin Plate.—Apart from ordinary small sales of spot stock and occasional orders for special sizes for near future delivery, there has been hardly any

business. The demand is quite as slow as it was at the beginning of the week, and, with liberal stock and good assortment, prices continue rather weak all along the line.

Chicago Report.

Scrap.—The following buying prices are quoted by dealers, but trade is very quiet.

	Per net ton.	Per lb
No. 1 Wrought Scrap	$10.00	....
Machinery Cast	7.50	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	5.00	....
Burnt Iron and Grate Bars	4.00	....
Sheet Iron and Hoops	3.00	....
Plow Steel and Breaking Stock	6.00	....
No. 2, such as Shovels, Hoes, &c	4.50	....
Old Boilers—whole (Iron)	6.00	....
" (Iron)—cut in single Sheets and Rings	9.00	....
Old Gas-Pipe and Boiler Tubes	6.00	....
Cast Borings	3.50	....
Turnings	5.00	....
Horseshoes	10 00	....
Copper Bottoms	....	7 ¢
Copper Clips and Heavy	....	8½¢
Heavy Brass	....	7½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2½¢
Zinc	....	2¾¢
Rubber	....	2¾¢

Anthracite.—There is very little doing. Dealers quote carload lots of 12 net tons as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

ELSEWHERE in this issue John P. Schaffer of 18 Wood street, Pittsburgh, Pa., directs the attention of the trade to the Novelty Ventilated Wall Pipe for which he was granted patents some time ago. The statement is made that this Wall Pipe is manufactured of best Bright Tin, by machinery designed specially for the purpose, and is turned out in lengths varying from 1 inch to 8 feet. The joints are double seamed, and the pipe is constructed in such a manner that if it becomes necessary to shorten it this can be done simply by removing the socket end, cutting off the pipe and replacing the socket in a few moments. Mr. Schaffer has already furnished a large amount of this Wall Pipe, and we are advised that it has given excellent satisfaction wherever used. Attention is also directed to the fact that it is claimed to be absolutely fire proof, which adds very materially to its value.

CONDITION OF THE

Hardware Trade.

THE PAST WEEK has been uneventful in Hardware circles, with few and unimportant changes in price. Trade, as expected at this season, is quiet and owing to the financial conditions is of smaller volume than usual. Retailers, as indicated in the reports given in our last issue, which are confirmed by others which the pressure on our columns will not permit us to publish, are feeling the effect of the financial stringency to a greater or less extent, some of them, however, having, up to the present time at least, a good volume of business. Collections, however, on the whole, are difficult. It is, as yet, too early to expect the opening of fall trade. Business is, to a large degree, limited to small orders for special requirements. Travelers generally are at home. Jobbers are wisely refraining from efforts to force business. It is also the vacation season and many are giving their attention to pleasure and recreation. Manufacturers generally, as reported in our last issue, are diminishing their production, working either on short time, or for the time being closing their works. The improved feeling in financial affairs is a matter for congratulation and it is hoped that before long the conditions will be favorable to a resumption of business in good volume.

Advices from Chicago.—Hardware collections are still improving, but trade does not gain in volume. Jobbers state that they are now withdrawing their travelers, and some are cutting down their working force at home. Salesmen are told to take plenty of time to see the World's Fair. It is seen that under existing conditions it is useless to endeavor to force trade. Jobbers are scrutinizing credits very closely, and are often refusing to book orders, although desirous of making better sales. Manufacturers of Hardware are now making unusually low prices on some articles for spot cash. It is a great opportunity for those having ready money, but as usual, opportunities of this kind come when most people do not have cash to embrace them. The dullness is felt both in Shelf and Heavy Hardware, but the decline in business is not quite so great in Heavy Hardware, as the small consuming manufacturers appear to be still driving ahead, and are purchasing material in reasonably good quantities.

Notes on Prices.

Cut Nails.—Many of the mills are shut down for repairs and in order to avoid an accumulation of stock. The volume of business is small and transactions are limited for the most part to small lots which are required for early use. There is an entire absence of speculative buying. Quotations remain on a basis of $1.05 for car load lots at mill, a figure which is slightly shaded in special cases. Iron Nails are obtainable at a concession of 2 or 3 cents from the above figure. Small lots from store in New York are quoted at $1.30 @ $1.35.

Advices from Chicago.—Although the Cut-Steel Nail factories are shut down, as far as can be learned the market does not appear to be in the least affected. Orders are very slow about coming in, and, when received, call for only a carload or so at a time. Inquiries are extremely light, and there is no indication as yet of any improvement in this branch. Factory prices are continued at $1.20 @ $1.25 Chicago, while small lots from stock are selling at $1.30 regular and $1.25 for quantity.

Wire Nails.—There have been no important developments in the Wire-Nail market during the past week. Quotations remain on a basis of $1.35 for carload lots at mill. Manufacturers are not endeavoring to force sales and are adhering pretty closely to the above figure. It is understood, however, that it has in some cases been shaded.

Advices from Chicago.—Manufacturers are doing a carload business almost exclusively. Jobbers have stocked up well, and it will be some time before they are again in the market to renew their orders. The closing of the Wire-Nail factories is having increasing effect in breaking the stocks of manufacturers, and more of them are reported to be buying from each other in order to make up assortments. Prices have not stiffened, but are still quoted on the basis of $1.45, Chicago, for factory lots. Small lots from stock are selling at $1.60, and quantities at $1.55.

Barb Wire.—The Barb-Wire market is sluggish and unchanged. The volume of business is small and prices are surprisingly well maintained. We continue to quote $2.45 to $2.50 for carload lots of Four-Point Galvanized at mill. Small lots from store are held at about the usual advance.

Advices from Chicago.—Business is extremely light from factory and from jobber. Prices have been reduced, the consolidated Steel & Wire Company having issued a new card on the Baker Perfect Wire, naming carload lots Painted, $2.20, and Galvanized, $2.60, usual terms, 60 days, or 2 per cent. discount for cash; Annealed Staples, carloads, $2.20 for Painted, and $2.60 for Galvanized; Polished, 10 cents per 100 advance. Ordinary Standard Wire is quoted at $2.10 for Painted, and $2.50 for Galvanized, but concessions are made to the best trade. Small lots from stock are still quoted by jobbers at the old rate of $2.30 for Painted, and $2.70 for Galvanized, but there is almost nothing moving.

Wringers.—We give below revised prices on Wringers, issued under date July 1 by American Wringer Company, 99 Chambers street, New York. For

the convenience of the trade, changes are indicated in full-face type. Most of these, it will be observed, are in the way of reduction, though in some instances prices have been advanced. Terms, 60 days, or 2 per cent. discount for cash in ten days:

Jack Chain.—A revised list of Brass and Iron Jack Chain has been adopted by the principal manufacturers of this line of goods. The list in its present form corrects the inequalities of the list adopted last March. No changes have been made in the prices of Safety Chain. The present list on these goods bears date July 10, and is subject to a discount of 60 per cent.

Odorless Stew and Fry Pan.—This pan has been put on the market by the Wilmot & Hobbs Mfg. Company, 20 Murray street, New York, and Bridgeport, Conn. It is sold to the trade at $1.25 each, subject to a discount of 50 per cent.

Glass.—The Glass market continues quiet and without noteworthy features. Stocks of Window Glass, while not large, are probably sufficient to meet the demand during the present shut down of the factories. The outlook for fall trade is regarded by some as very encouraging, confidence being expressed that a business of gratifying proportions will then be done. These observers make the point that the present slowness is not due so much to overproduction as to the fact that many projected enterprises have been suspended or retarded by the existing financial difficulties. Others, however, refer to the future in a less hopeful vein. The meeting of the Wage Committee of the Glass workers and the manufacturers which was announced to take place today has been deferred, and it is likely that it will not be held before next month. The demand for American Plate Glass is somewhat sluggish, although stocks are being perceptibly reduced. There is perhaps a slight improvement in the demand for imported Glass and collections are also said to be somewhat better than for some time past. Quotations on Glass remain unchanged, as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Trade Notes.

CHARLES WEILAND has recently taken possession of his new quarters at 149 Chambers street, three doors below his former stand, having leased the entire building, containing in all seven floors 22 x 70 feet each. In addition to the jobs in Hardware, Tools, &c., heretofore dealt in, a line of Blue and White and Gray Steel Enameled Ware for kitchen and housekeeping purposes has just been taken on. He recently purchased 1500 cases of the Haberman Mfg. Company at auction in this class of Ware.

WADDEL WOODEN WARE WORKS, Greenfield, Ohio, are manufacturing a combination Paper Weight, Puzzle and Game, which they designate "Nip and Tuck." "Nip and Tuck" is a recent invention of Mr. Waddel. The device is referred to as beautiful in design and finish, and attention is called to it as an excellent advertising medium as well as an article of sale.

A NEW Copper and Brass Goods house has been established in Chicago by the Mortimer McRoberts Company. Mortimer McRoberts, the president of the company, has long been known to the Western Hardware trade. M. H. Kiebel, the secretary, and S. Rose, the treasurer, are also men of experience and wide acquaintance. Associated with them are F. E. Pomeroy and J. P. McCreedy. They opened temporary quarters at 90 Market street, Room 305, but will hereafter be located at 230 Lake street, where they will carry Sheet and Roll Brass and Copper, Brass and Copper Wire, Bare and Insulated Electric Wire, Rods, Tubing, Rivets, Pins, Chains, Lamps, Lamp Trimmings, Shades, Wick, Oil Cans, Furniture Trimmings and Sheet Metal Goods in great variety, being direct and sole representatives of leading manufacturers.

GEORGE GNAU, for many years past representing the interests of the Cincinnati Stamping Company, has resigned his position as traveling salesman and will hereafter represent the well-known tinners' supply house of Mathai, Ingram & Co., Baltimore, Md. Mr. Gnau will cover the same territory as in the past, making his headquarters at Cincinnati.

THE BELLAIRE STAMPING COMPANY of Harvey, Ill., call attention in another part of this issue to the Columbian Enameled Ware which they manufacture. Reference is made to seamless Drip Pans, Zinc Oilers, and Plain Stamped and Retinned Ware.

"THE TAYLOR ROOFING TIN" is the subject of an announcement published elsewhere in this issue by the N. & G. Taylor Company of Philadelphia. This roofing Tin is said to be very heavily coated and made of the finest quality of rehammered Siemens-Martin Soft Steel. The coating is referred to as being uniformly and evenly distributed over the entire sheet by a special process, and that each sheet is stamped with brand and thickness.

FERNANDO B. SMITH, Canton, Ohio, keeps quite a large force of tinsmiths busy turning out Smith's Patent Force Sprinkler and Novelty Pump, which is made of tin and furnished with several different nozzles and roseheads for spraying trees, vegetables or washing windows and carriages. A circular sent with the Pump explains its use and gives a number of safe recipes for fluids for the destruction of insects.

Mineral Wealth of South Africa.

In a paper read a short time ago before the British Society of Arts, in London, Bennett H. Brough, in describing the mining industries of South Africa, stated that of diamonds alone $3,600,000,000 worth have been mined in that region during the past 20 years. Gold was first mined in the Transvaal about five years ago, and already the output has been $42,500,000, while it is expected shortly to reach over $20,000,000 annually, exclusive of the products of Mashonaland and other parts of the country. But it is not in these precious minerals alone that South Africa's mineral wealth consists. We learn that her coal fields are of vast extent, although the coal industry is still in its infancy. Of copper 20,000 tons are produced yearly, and many other metals occur in great abundance. At an exhibition lately held at Kimberly, the capital of the diamond fields district, some extraordinary examples of minerals were shown, as well as some relics from the interesting ruins of Zimbabye, which have puzzled archæologists on account of the evidence they give of the existence of an advanced condition of civilization in that part of Africa in very ancient times. Among these exhibits was a mold for a gold ingot exactly of the shape of the tin ingot dredged up from Falmouth harbor, Cornwall, in 1811, and which corresponded with the form of ingot described 1900 years ago by the historian Diodorus Liculus. There is, says Mr. Brough, reason to suppose that the Phœnicians who pushed their adventurous barks to the distant British Isles and dropped the ingot in Falmouth harbor, were also responsible for the remarkable ruins of Zimbabye. In spite of its enormous mineral resources, however, Mr. Brough cautions those who may be tempted to try their fortune in South Africa that the supply of white labor there is already in excess of the demand. Skilled workmen are, however, well paid in the towns.

We have been favored by the State Board of Health, Lansing, Mich., with a copy of the eighteenth annual report of the board for the year 1890. The statistics given therein in relation to diseases in the State of Michigan are very extensive, and will be valuable to sanitarians. Interesting papers are included in the report on the "Principal Meteorological Conditions in Michigan" and on "The Time of Greatest Prevalence of Particular Diseases." Casualties from the use of gasoline form the subject of a special table. These amounted to nine in the whole State during the year, nearly all of which were the result of carelessness in handling the oil.

Crossing Rivers on Air Floats.

The transportation of troops across rivers by means of air floats made of the hides of animals has been the subject of extended experiments recently by the Russian military authorities. This system of transportation is described by a French military review, and highly recommended as offering advantages which would make it of much use in great military campaigns: "The large number of animals daily slaughtered for the food purposes of an army furnish ready means of obtaining the hides required in constructing the floating rafts, and at much less expenditure of time and labor than would be required in constantly transporting a pontoon train. The floats are made in the following manner: After the animal has been killed the hide is cut only where necessary and carefully removed. The neck portion is closed by a number of stitches, and the openings of the legs and tail are encircled by strong cords. A tube is inserted into one of the leg openings, by means of which the hide may be blown full of air. The tendons of the animal furnish the necessary cords for binding the various parts together. The hides, after being filled with air, are placed beneath the rafts, one at each corner. So buoyant are these air floats that by their aid a large number of soldiers or heavy pieces of artillery may safely be carried across rivers or other bodies of water."

Although this method of crossing rivers is pronounced a novelty in transportation by the review above quoted, the Russians are actually by no means the first people who have availed themselves of this expedient. It is, in fact, but another illustration of the truth of the Wise Man's dictum that "there is nothing new under the sun." The traveler in upper Egypt and Nubia today may see the natives of that portion of the "unchanging East" practicing this method of crossing the Nile, as their progenitors did 3000 or 4000 years ago. With the aid of bladders and skins they regularly transport themselves and their goods and chattels—the latter on their heads—from one side of the river to the other; and this practice is employed by the inhabitants of various other parts of the African continent. Moreover, the use of inflated skins for transporting an army over rivers was adopted by the troops of Xerxes long before the Christian era, and the expedient has been, in modern times, utilized on more than one occasion by the British troops in India. Instances might be multiplied of the antiquity of this supposed "novel" method of transportation, which is, indeed, as old as history.

Dr. Haffkine, a German physician, has inoculated numbers of European residents in India for cholera, including British officials and the officers and men of several regiments. His system has been received with great favor by the rulers of several native States, who are about to adopt it in their dominions.

The Cramps have received a check from the Government for the sum of $900,000, of which $700,000 was in payment for work on the "New York," and $200,000 for the bonus earned by that boat for exceeding the required speed.

Two steamers for service between Buffalo and Duluth are now being built by the Globe Iron Works of Cleveland. These ships will cost $600,000, have quadruple expansion engines, 25, 36, 51½ and 74 inches diameter, of 7000 horse-power; all valves of the piston type. The length is 380 feet, beam 44 feet, depth 34 feet. They will be provided with 28 boilers of the Belleville type.

An extraordinary series of frauds has been disclosed in connection with the building of two iron bridges across the Lachine Canal at Montreal, Canada. The stone was hauled by teams owned by members of the Provincial Legislature for 20 miles, from the quarry to the works, at the rate of only one load a day, although a railway ran into the mouth of the quarry. Thus the stone which should have cost $5 a cubic yard actually cost $59.

Probably few people realize the large amount of work which is regularly carried on at the Brooklyn Navy Yard. Thus in the construction department alone 740 men are at present employed in repairing the war ships.

The total receipts of the New York post office for the fiscal year ending June 30 were $7,369,260 52, an increase over the preceding year of nearly $600,000.

Note.—The quotations given below represent the Current Hardware Prices which prevail in the market at large. They are not given as manufacturers' prices, and manufacturers should not be held responsible for them. In cases where goods are quoted at lower figures than the manufacturers name, it is not stated that the manufacturers are selling at the prices quoted, but simply that the goods are being sold, perhaps by the manufacturers, perhaps by the jobbers at the figures named.

The character @ is used to indicate a range of price; thus discount 50&10@50&10&5 % signifies that the goods in question are sold at prices ranging from discount 50 and 10 % to discount 50 and 10 and 5 %.

News and Notes.

The elevators and storehouses of New York are congested with wheat awaiting transportation abroad. The low cargo rates prevailing have led to few offerings by the steamship companies, and as a result every available storage building has been taxed to its utmost by the influx of grain from the West and even a great number of canal boats have been unable to unload their cargoes.

There were 887 business failures in the Canadian Dominion during the first half of this year, according to *Bradstreet's*. The liabilities aggregated $8,215,759, against $3,880,236 of assets. As compared with the same period of 1892, this represents a falling off in number of 7 per cent. and an increase of about 14 per cent. in liabilities.

The United States Consul at Batoum, on the Black Sea, has made an interesting report on the development of the petroleum oil trade at Baku, on the Caspian Sea. The general conclusion arrived at is that, in spite of the immense supply of oil, the increasing demand may exhaust it. The daily yield of crude oil in 1885 was 38,000 barrels, and in 1892 it had increased to 110,000 barrels, while during the month of May it ran up to 137,000 barrels per day.

The French War Office has had submitted to it an electric gun alleged to be capable of discharging 25,000 projectiles in five minutes and to have a range of several miles.

Letters from Caracas to merchants in the South American trade indicate that Venezuela is at last at peace. It is stated that President Crespo has submitted to the new parliament a proclamation pardoning all those who fought against him. The act has been approved and all natives of the country can now safely return.

The American Society of Civil Engineers has issued a reference map of the United States for the convenience of visiting foreign engineers. It contains an extensive list of public works and manufactories which are open to their inspection, the map and lists having been prepared by the Committee of Information and Courtesy, of which Edward P. North, Leffert L. Buck and Foster Crowell are the members

In the United States Circuit Court at Pittsburgh last week opinions were handed down in two suits for infringement of patents. One case was that of the Duff Mfg. Company against William Forgie, and the other that of William Forgie against the Duff Mfg. Company and the Oil Well Supply Company. The first suit was on a jacking mechanism for screwing and unscrewing oil-well tools, which is covered by three patents held by the plaintiff. The court held several of the claims in two of the plaintiffs' patents had been infringed by the devices used by the defendant, and a decree against him was directed to be drawn. In the other case on other devices, for which Forgie claimed to have patents, the court held his patent is invalidated because of the non patentability of the device. Judgment for the defendant was therefore given.

A splendid system of electric buoys has been inaugurated by the Lighthouse Board for lighting the lake front between Chicago harbor and the World's Fair grounds. This system of lighting might be advantageously introduced in other inland waterways.

The London & Northwestern Railway Company have begun an experiment in running what they term "corridor trains," which correspond with our vestibule trains, on their line between London and Edinburgh. In constructing the cars for this new train an effort has been made to combine the conveniences of the American system with those conditions of semi privacy that are considered desirable in English railway carriages. The cars, both first-class and third-class —for the second-class cars have been discontinued—are built with a corridor running along the left or platform side of the carriage, instead of having a central passageway, as is usual in American trains. The space not occupied by the corridor is divided into compartments in the usual way, each compartment affording accommodations for four passengers. The passage from one car to another is effected by an arrangement which resembles our vestibule device, except that the covering is of stout india rubber, fitted to metal frames.

A successful trial has been made on Long Island of an underground electric railway system, for which claims of advantage over the usual trolley system are made.

The new Walnut street bridge, Philadelphia has been opened to the public. The bridge has been in course of construction since June, 1889. Its erection was authorized and an appropriation of $200,000 to begin the work was made on December 24, 1888. Work was not commenced on the piers, however, until September 20, 1889, when the contractors began the eastern one. On November 9 this was carried away by a freshet. Work was then begun on the western pier. Considerable difficulty was met with in constructing the piers on account of the depth of water. The four piers were finally constructed, however, at a cost of $120,000. There are three spans over the river 123 feet long. The total cost of the structure was $741,418 64.

One important result of the armor-plate tests made at Indian Head last week will be to extend the use of the Harvey process. The tests were satisfactory as far as they went, but the Secretary of the Navy is reported to have reached the conclusion that, while the plates were as good as could be expected from plain nickel steel, they did not show the resisting power of Harveyized nickel-steel plate. This will mean much to the manufacturers of armor plate. The contracts under which the plates are made permits certain pieces to be made of plain nickel steel. The reason for this is that the Harvey process is very difficult of application to curved plates or pieces of irregular form. Such pieces are very apt to warp when submitted to the process, and as they emerge with a surface almost as hard as a diamond it is said by the plate makers to be next to impossible to do anything with them in the way of manipulation. The warping frequently throws the bolt holes out of line and distorts such pieces as the sponsons, the semi-cylindrical pieces that protect the guns on the side of a ship, so that they will not fit, and the work of adjustment is very difficult and tedious, as few tools can be made to cut the hardened plates.

It is stated that franchises are being gradually secured with the ultimate object of connecting Philadelphia and Newark, N. J., by trolley railway lines.

The London *Times*, following what has become its usual practice, has published an exhaustive review of the acreage and condition of crops in Great Britain, based upon replies to special inquiries addressed to all sections of the country. A decreased acreage is shown for wheat and barley, but oats, potatoes, beans, peas, roots, grass and hops all show increases. Speaking of the unpromising conditions, the *Times* says that if the farmers are to escape actual ruin some unforeseen and fortunate circumstances must arise.

Boston advertises for bids for the construction of a dam across the valley of Stony Brook. This will make a basin holding 7,500,000,000 gallons. The work must be finished by November 1, 1896.

Announcement.

The publication of *Metal* by the Kittredge Company, 78 Reade street, New York City, has ceased, and the journal has been incorporated with *The Metal Worker*. Unexpired subscriptions to *Metal* will be filled by *The Metal Worker* for the time for which payment has been made.

The acquisition of this journal will in no way affect the policy or conduct of *The Metal Worker*, which will continue to be published in the interests of the several classes to which it is addressed. The practical features of the paper will be increased wherever and whenever possible, and the news of the trades will be fully presented. It is not proposed to change the standard of the paper in any way, except to improve it whenever occasion offers. With this purpose in view, the co-operation of the readers of *The Metal Worker* is cordially invited, and it is desired that they continue to write freely when they are seeking information or have anything of interest to tell the trade.

Photographing Plant Growth.

Photography has in many ways been serviceable to modern science. In almost every branch of physical research its aid has been called in to record facts, phases and discoveries, the impression of which, often of an evanescent nature, could not by any other means be caught and permanently retained in evidence. Fresh applications of this valuable art are being continually reported. The camera's aid has brought to knowledge, in combination with the refracting telescope, stars and heavenly bodies not visible to the human eye even when assisted by the most powerful instruments. Muybridge has succeeded in obtaining that most wonderful series of photographs of the movements of the horse, which has taught artists and naturalists more about animal locomotion than they ever dreamt of before. Only recently we read that the characteristic walk of certain insects had been absolutely defined by photography. Similarly the camera has accurately registered the movements of a bird's wing in flight. Even the play of the lightning flash has been followed and recorded. There seems to be practically no limit to the usefulness of photography in the arts and sciences. Its latest development, as noted in an exchange, is the application of photography to record the movements of the growing parts of plants, by which some curious results have been obtained. In the case of the hop convolvulus, the movements of the young stems were found to consist of a succession of irregular circular or elliptical curves, which vary every moment, even in their direction. These movements are caused by unequal growth in different parts of the stem. It was also discovered that even when asleep plants move, not, as was formerly supposed, interruptedly, but continuously. Further interesting disclosures will probably be made in this field by the help of the camera.

Summer Ventilation.

At no time in all the year is ventilation more ardently sought than in this time of thin clothes and cooling beverages. And yet it is not ventilation in its true sense that is always sought. Comfort to the ordinary man comes rather from an appreciative movement of the air than from a mere preservation of its quality without drafts. The palm leaf, as well as the whirring electric fan emphasize this most strongly. And yet what we really require is an atmosphere cooler than that in which we are suffering. This can seldom be obtained except by expensive appliances. The supply of large air volumes by means of a fan meets the requirement only in so far as quantity is concerned, but quality, as necessary to the desired result, must be measured by a lower temperature, and, even more important, by an atmosphere that is dry enough to readily absorb the moisture emitted by the skin, but still not so dry as to have the least effect of parching. The great difficulty with most cooling devices is that either cold water or ice is employed, the air being brought intimately in contact with it and thereby charged with moisture. At the same time the temperature of the air is reduced and hence its own relative humidity increased. This latter is likewise true of air cooled by contact with refrigerating pipes. It has been suggested that the air, prior to its cooling, might be passed across trays of calcium chloride, which is a greedy absorbent of moisture, and thereby be dried to such an extent as to make it possible to cool it to the desired degree without objectionably raising its relative humidity.

Salary vs. Opportunity.

Too frequently the young man seeks first and most earnestly for a paying position. It is too much a matter of a bird in the hand being worth two in the bush. But the day comes when the young man, now older grown, finds that he has practically reached the limit of his opportunity with the person or concern by whom he has been employed. The boy who settles down to learn a trade, although his first few years may be years of hardship and deprivation, will, with persistence, reach and surpass his rival who has taken a position which is limited in its possibilities, or which is such as to give him no valuable fitting for a position elsewhere.

Too Small Capital.

With the recurrence of hard times and the multiplication of failures on every hand, a great deal is heard of the good effects that will be accomplished through the permanent retirement of those who have been trying to do business on too little capital. This is a theme which is dwelt on in every circle, and the small merchant, whose utmost credit is measured by hundreds, applies the criticism as glibly to his weak competitors as does the millionaire operator to his weaker rivals. It is recognized that every line of trade has in it a number of weak concerns that even in good times are tottering on the verge of bankruptcy, because of too great an extension for the capital invested. And men argue that if only these lame ducks could be driven out of business everybody else would have a much better opportunity. Prices would be more stable, because there would be no one making occasional forced sales to raise money or offering inducements of an exceptional character to increase trade.

Forced Sales.

Proceeding upon this line of argument, men are apt to draw distinctions and term some business houses illegitimate or irregular. They are thus characterized solely because they do not have sufficient capital to conduct their operations in the conservative, staid, dignified manner peculiar to con-

cerns with unlimited bank accounts or unlimited credit. They are obliged to make a raid on the market when a little pinch comes, and cut prices so as to make a line of goods move quickly and bring in the requisite cash. They are apt to break out most unexpectedly and of course always most disadvantageously for their competitors who would encourage stability and deplore distressing fluctuations. The hardware and kindred trades do not suffer much from "fire sales" and from "misfits," it is true, but there are equally annoying circumstances to vex the sturdy merchant who discounts his bills and expects all his customers to do the same.

Cheap Credit.

Credit has perhaps been too cheap in the recent past. The point had almost been reached when a man could go into business with no capital whatever and obtain credit at a dozen different sources of supply. He could certainly command a credit of several times his cash resources. Every creditor knew that he was buying from others at the same time greatly in excess of his capital, and yet there was no protest at the great expansion in business thus promoted. Orders had to be obtained, because small margins made it necessary to do a large business, and the dance went on. Sometimes the banks were imposed upon by this class of people representing themselves to be exclusive customers, slipping in back doors, because they did not want it known that they were borrowers of money, yet using every bank in their vicinity in the same way until the bubble grew too big and finally burst. These are the people that straightforward business men would be glad to see permanently retired. Many of them have been relegated to the commercial graveyard already, and others will follow as the monetary pinch retains its hold. Unfortunately, these people do not go alone, but take company with them worthy of a better fate.

Cash Business.

Out of these tight times we will emerge presently on a much better basis. Business will be done more largely for cash. Credits will be very carefully scrutinized. It will not be an easy matter for a merchant to buy goods to the full amount of his capital from a dozen different houses and trust to good luck to pull through. That time will come only after the country has enjoyed a long season of prosperity again and forgotten all about the panic of '93. Meantime energetic men of small means will find it much harder to get a start in the world than from '80 to '90. It will not do to refuse credit to all of them, establishing a cast-iron rule on the subject, as that would kill all enterprise and prevent perhaps most capable business men from getting a good foothold in the great struggle for supremacy.

Indianapolis, Ind., has adopted the plan of cremating her city garbage.

In Memoriam.

The following letter from ex-Senator Dawes of Massachusetts has been furnished us for publication. Mr. Dawes, who knew Colonel Auchmuty in his country home at Lenox, tells how he was always working for the good of others and did not limit his benefactions to his cherished trades school.

PITTSFIELD, MASS., July 25, 1893.

I am very glad to comply with your request, and avail myself of the opportunity to bear testimony to the great work and worth of the late Colonel Auchmuty. Although his summer home here in the country is many miles from the noble work to which he devoted so much of his time and money, yet we here saw in our daily intercourse with him what manner of man he was, and were made acquainted with those traits of character out of which came the trades school of New York and the many other benevolent enterprises which he had so much at heart. He brought with him here—indeed, he carried with him everywhere—a great heart, an earnest zeal to do something that would help those around him to the opportunity, to the desire and to the ability to better their own condition. It was along this line that his interest lay—to help men to help themselves. He was, above all, a public spirited man, and identified himself with every undertaking tending to the improvement of his city and town, as he had given himself in the past to the nation in its time of need. We saw much of that spirit in his work at Lenox, where he devoted much time to promoting and superintending works for the improvement of that town. Much of the liberal and public-spirited effort which has made it not only beautiful and attractive, but safe and wholesome as well, by means of its roads, its water supply and sewerage, and other permanent improvements, is due to the inspiration, personal effort and example of Colonel Auchmuty, one of the first among the summer comers and earliest among those who set about doing the best possible thing for Lenox. There is not a charity or other good work in that town which will not feel his loss, and especially will this be true of the publicschools.

We knew little of the methods of the trades school founded by him in New York, but we knew of the good it was doing. Boys from the vicinity of his home here have been the recipients of its benefits, and have come back equipped for a useful life and resolved on its accomplishment. Colonel Auchmuty impressed those with whom he came in contact with the feeling that the endeavor of his life was to lift—to lift those who needed a lift in whatever way opened. The needy and the worker alike have lost a most efficient helper, those who have money and a heart to use it for their fellows, a most worthy example, and the community in which he lived a most estimable citizen.

He won the regard of all, and the lasting gratitude of many a useful and valuable citizen who but for him would have gone through life, if not a positive curse to society, a helpless and useless incumbrance. He will be missed and mourned by all who knew him.

H. L. DAWES.

We print below a letter from Harry Brill, who is well known to the graduates of the New York Trades School, and who, from his intimate acquaintance with Colonel Auchmuty and his work, understood better than others the relationship he held toward the students:

NEW YORK, July 25, 1893.

In the death of Col. R. T. Auchmuty an inestimable loss has been sustained, not only by the school with which his honored name will always be associated as its founder and sustainer, but also in educational circles where his thorough knowledge and familiarity with the subject of instruction in the mechanical trades was of incalculable value, and greater than all will his loss be felt by the army of young men whose welfare he constantly sought to promote.

In the many tributes to his memory that have recently appeared, extended reference has been made to his life and to the trades school he built, to his high character, noble purposes and benevolence; but only to those most intimate with him was the absorbing interest he took in young men familiar.

Nothing afforded him greater pleasure than to personally be among the students, observing their progress, speaking words of sympathetic encouragement, imparting kindly advice and endeavoring to make brighter the trying road each was traveling in his efforts to acquire a trade that would insure an honorable livelihood. On frequent occasions a student, becoming disheartened for the moment at not immediately attaining success in some difficult piece of work, obtained renewed determination not to fail through the influence his presence exerted.

That the young men appreciated the fatherly interest he took in their life is attested by the enthusiasm with which he was always greeted and by the innumerable letters received by him from those who have attended the school.

A few years ago, in an address made in Philadelphia, he said: "I propose to devote the remaining years of my life to the American boys." How faithfully and unselfishly he has done so is too well known to need repetition.

Although Colonel Auchmuty has passed away, the institution which he leaves will continue to shed its usefulness in the future as it has done in the past.

HARRY BRILL.

From Edward Murphy, a master plumber, widely known throughout the country and who has taken much interest in the New York Trades School, we have the following appreciative letter:

NEW YORK, July 26, 1893.

A subdued and hushed air hung over the village of Lenox, amid the Berkshire hills in Western Massachusetts, as the simple funeral cortege conveying the remains of the late Colonel Auchmuty wound its way down the mountain road from his residence to the church where the final rites were performed.

The stately edifice, which stands as an enduring monument of his architectural skill as well as of the munificence of himself and Mrs. Auchmuty, was filled with his relatives, friends and the residents of the neighborhood. The simple and impressive services occupied all too short a time, and on the invitation of the Rev. Dr. Huntington, one of the officiating clergymen, the entire assemblage followed the funeral to the ancient cemetery where so many of the forefathers of the village hamlet sleep.

The last sad tribute of reverence and affection was paid on a grassy slope of the hill side facing the west, the rays of the setting sun gilding his resting

place, and the thought involuntarily came into the mind how fitting and peaceful was the close of the earthly career of one of the noblest and most self-sacrificing men of his generation. A man of large means, cultivated tastes and historic record, he identified himself with a new departure in the history of the world's well-doing. For many years he devoted himself heart and soul to a cause that appealed intensely to his sense of justice and patriotism. He saw the young men of his native land debarred by senseless and galling restrictions from their natural opportunities of acquiring the knowledge of various trades and unhesitatingly he resolved to right this wrong as far as in him lay. With infinite pains and assiduity he elaborated and carried into effect his plans for a school where the more important of the building trades could be taught. The difficulties he met with and the discouraging opposition that beset the pathway not alone of him, but of all who run counter to the antique prejudices of average humanity, is known but to his intimate friends.

It is one of the tritest of sayings that nothing succeeds like success, and of those now ready to applaud the splendid results and untiring efforts as evidenced in the work of the well-known New York Trades School, could but realize the time, thought and expense involved, they would be amazed at the magnitude of the undertaking. And all this was done without parade, without notoriety seeking or appealing for outside aid, and it is within the bounds of strict truth to say that as an individual enterprise the school is to-day unparalleled in the world's history.

And now a word as to the future. As recently organized under a board of trustees, whose names are synonymous for executive ability, intelligence and wealth, it would be difficult to set a limit to the progress and development that may be expected hereafter. While the changes thus made conduce immensely to the success of the school, it may be well to say that in any event ample provision was made for its continuation on the lines already laid down by Colonel Auchmuty, for, as he declared on more than one occasion, it was his purpose and determination that, no matter what happened, his life-work should not die with him, but should be perpetuated for all time.

EDWARD MURPHY.

Natural Gas.

BY L. M. W.

It is generally known that natural gas gushes up out of the well and doesn't have to be pumped out, but only a vague idea exists as to the force with which it comes. The highest pressure reported was found in a Canada well, which was calculated at 700 pounds to the inch. A few have been found in the Pittsburgh district that have run up to 500 pounds, while a pressure of from 300 pounds up to 350 pounds is not uncommon. At a manufacturing plant at Gas City, Ind., that had not yet got the boiler in operation, a gas-pipe was connected with a pumping engine instead of the steam pipe, and no difficulty was experienced in pumping water from a well 280 feet deep. In using the gas for fuel it has been found necessary to use pressure regulators to reduce the pressure to about 8 ounces, which seems to be most satisfactory. One ounce or an ounce and a quarter is about the usual pressure found in the artificial gas manufacturing plants of the average city. In many sections where there is an abundance of natural gas, the right to bore for gas is leased by a syndicate from the owners for all promising land near a given center, where, as an inducement for manufacturers to locate, a plot is given and gas furnished for fuel free of charge. As a result economy of consumption or perfection in combustion is given little consideration and leaks and wastes impart a perceptible odor to the atmosphere. In some cases a blower is used to force air into a mixing chamber with the gas to secure a clean flame and a high temperature.

In the tin-plate plants workmen who have formerly used coal are quite enthusiastic over natural gas. It supplies an even temperature, never making the plates too hot or too cold (to demand extra work or loss of time) and there is no replenishing of fuel or stoking necessary, consequently more work and wages result.

For light forging an oven or furnace, built of brick, is used for heating the iron or steel. The ovens are of various sizes, set on iron legs of convenient hight, and consist of two thicknesses of brick on the bottom and on the top. One in mind had side walls about 14 inches high on the outside and was 24 x 36 inches in size, with an opening 4 inches high across one side, through which the material was inserted. On looking inside no flame was apparent, but a bright red heat was clearly perceptible and the blacksmith had no difficulty in shaping his work when placed on the anvil.

In the brass foundry a flame encircles the crucible and frequent heats can be readily made.

Plumbago Foundry Facings.

The Joseph Dixon Crucible Company of Jersey City, N. J., have issued the following interesting statement: In considering the subject of foundry facings the art of molding may be divided into three classes — viz.: 1. Green sand. 2. Dry sand or loam. 3. Flat or "print-back" molding. Such a division answers to the three general methods in which facings are applied.

But in different shops different conditions exist and different methods are followed, and because of their differences we are often unable, through our ignorance of them, to correctly fill orders that come to us.

For your better information we give a short description of the three methods of mold-making and using of facings.

1. In green sand molding, the sand (slightly damp, just enough so to pack and retain the form of the pattern) is rammed around the pattern, the pattern is removed and the facing is applied. This is done either by shaking the facing through a bag or by being put on with a brush, to insure its even distribution over the surface of the mold. It is then rubbed by the hand or by the use of a "sleeking" tool. This insures the adherence of the facing to the moist sand so that it will not run or become loosened, as the molten iron runs across it.

This method of making molds is used more than any of the others and is used in all general machine shop work, except where the castings are very heavy.

2. The dry sand or loam molding is employed. In this branch of work, dry sand—that is, sand that has previously been used in the same kind of work, is mixed with fresh loam, and after the molds are made they are baked by placing them in an oven if small, or by building a fire inside the mold if they are large. Such a mold is hard and firm and the surfaces are porous in texture and afford a fine support for the facing, which is applied in the form of a wash or paste. The usual sleeking follows, to insure perfectly smooth surfaces on the casting. This method is followed where the work is heavy—such as engine and planer beds, engine cylinders, large gear wheels, &c.

3. Flat or "print-back" molding is the method employed where the articles to be cast are light and ornamental in character—such as stove plate, grate fronts, castings and iron fences, &c. In this case the molds are made the same as in green-sand molding, and the facing is applied through a shake bag, but instead of smoothing the facing by the hand or tool, the pattern itself is pressed back into the mold, and in this way the facing is made to stick to the sand and also to correspond exactly to the surface of the pattern. Whatever loose facing may be left in the mold is blown out by the bellows and the mold is finished.

With this information in your mind, you are expected to put yourself in possession of such other information as will enable you to answer the following questions when sending in an order for facings:

1. What articles does the molder make?

2. (*a*) Which of the three methods are followed?

(*b*) If more than one method is used, for which method is the particular facing of this order to be used?

3. (*a*) If for green sand molding, is the facing to be applied through a shake bag or by a brush?

(*b*) Is the facing "sleeked" by the hand or by a tool?

(*c*) Are the castings heavy or light (that is, is the total surface of the casting small or great as compared with the weight)? This is important. A block 1 foot each way weighs the same as a plate 4 feet long by 3 feet wide by 1 inch thick. But the block has but 6 square feet of facing surface, while the plate has more than 25 feet. You wil see at once how differently the first cast ing would effect a facing.

(*d*) Does the foundryman consider that he uses his sand wet, dry or medium? Be sharp on this point, so that you may be able to judge for yourself. One man's "dry" sand may be another man's "wet" sand. By feeling of the sand in every shop you go into you will soon be able to judge on this point better than any molder in any shop.

(*e*) Do they have any trouble from the facing running before the iron?

4. If for dry sand loam molding, is any charcoal added to the facing by the molder himself?

5. If for flat molding, is charcoal used in connection with the facing, and if so, is it dusted on separately or mixed with the facing before using?

6. Are there any troubles in the conditions or practices of the shop that might bother the facing, and have there been any difficulties experienced in the use of his molding sand.

Nearly $9,000,000 were expended in Washington, D. C., during the year ending June 30, 1893, in building operations. The new houses put up within that period were 2720. This number would have been much larger but for the law recently passed which practically forbids houses being built in alleys in the national capital.

TIN PLATES.

What Is Tin Plate?

BY L. M. W.

On listening to the queries of the sightseer at the tin-plate exhibit at the World's Fair the lack of information and acquaintance with the features of tin-plate manufacture becomes conspicuous. The general but incorrect impression is that a secret and wonderful skill is required to plate the black sheets. In fact, in many cases, this all-important essential is a seemingly new thing to the inquirer. In the production of the black sheet from 80 to 90 cents is expended of every dollar spent in making tin plate. On the toughness of the fiber depends the value for working. On the even thickness depends its desirability and value for various purposes. On its surface depends the amount of material used and the ease of coating it. With the black sheets possessing all of these desirable features the coating is by no means a serious condition to meet and is readily overcome, as is shown by the 10 to 20 cents of the dollar which pays for both the pig tin and the labor. For some reason it is not generally known that the English tin-plate makers are just as far from the mines where they get their supply of pig tin as we are, and that the tin mined on the British Isles is not suitable for use in coating plates. We have lead at home for making terne plates, and have that advantage. The price of tin plate will always be sympathetic with the price of sheet iron, and not with pig tin, to so great an extent. The puddler and rolling-mill man, rather than the miner, will always exert the more potent influence on the tin-plate market. This does not seem to be the public opinion, but just think it over and the truth will become manifest.

Tin Plates for Cuba.

A Washington dispatch records the discovery that British tin plates have been lately introduced in considerable quantities into Cuba, free of duty, under the reciprocity treaty recently entered into between that island and the United States. It was found that a wonderfully large trade in tin plates had recently developed with America, while there has been at the same time a remarkable falling off of receipts from duties on English plates at Havana. Upon investigation by the Spanish authorities, it was found that large British shipments of tin plates and tin-plate hardware have been unloaded in the United States, marked "in transit," and that these goods, supplied in some way by the necessary certificates, manage systematically to get into Cuba, under cloak of the reciprocity treaty, without paying the duties which Spain exacts from all English imports. The Spanish Government has sent complaints to London and Washington, and the three governments are said to be now making efforts to stop the leak in the Havana customs receipts, to restore direct British trade, and to prevent the reciprocity treaty from covering fraud.

SCRAP.

A. A. THOMSON & Co., New York, are installing an additional tinning machine at their tin-plate works, which will increase their output 50 per cent. Messrs. Thomson report a very satisfactory demand for their product of roofing plates, which insures the sale of all they can put out, running their works to full capacity.

THE TERNE PLATES for roofing the new pier building for the Inman Company at the foot of Fulton street, New York City, were supplied by the N. & G. Taylor Company, Philadelphia. The pier, which is 650 feet long and 130 feet wide, will be the finest structure of its class in the North river and one of the finest in the country. Taylor Old Style, 1C, 20 x 28, is the plate used. The roofing is being carried out by Jacob Ringle & Son, roofers, of Jersey City.

THE HARRISBURG, PA., SHEET MILL of the Lalance and Grosjean Mfg. Company was lately shut down for three weeks, owing to lack of water. This defect has been remedied by the connection of the works with the city water system and the mill is again in full operation. The company report a large demand for their black sheets for tinning purposes. All the material that they do not consume at their Woodhaven factory is readily bought by the American tin-plate manufacturers.

BRITISH EXPORTS of tin-plates and sheets to the United States during the month of June were 26,759 tons, against 23,550 tons in the corresponding month of 1892.

P. W. SPENCE & CO'S CIRCULAR, dated London, July 11, has the following report on the British tin-plate trade for the first half of this year: "Tin plates receded still further during the half year, and now are at the lowest figures ever known in the history of the trade. This fall was caused by the reaction in the price of tin, following upon the silver crisis, and the slow demand experienced from the United States. The trade is undoubtedly very unprofitable to the makers, and any stoppage of production could not fail to affect prices. There is still great uncertainty as to when the McKinley tariff will be amended; but the American authorities have at last discovered that the quantity of tin plates made from native iron is very small, and that the great bulk of the so-called American tin plates are being made from English black plate. Exports of tin plates (January 1 to June 30):

	1893. Tons.	1892. Tons.	1891. Tons.
To United States	160,420	143,021	263,225
To Russia	15,273	15,781	11,818
To other countries	41,874	47,975	31,163
Totals	217,567	206,777	306,206"

JOHN HAMILTON, Pittsburgh, Pa., manufacturer of the well-known Hamilton best re-dipped American roofing plate, is receiving the hearty congratulations of his friends and the trade generally on the occasion of his marriage, which took place on Thursday, the 27th inst. The happy couple are now enjoying a tour of the Eastern watering places, and before returning to their future home at Bellevue, Pa., will make an extensive visit to the World's Fair. The warmest congratulations of *The Metal Worker* are extended.

LATEST ADVICES from England report business as still dull in the tin-plate trade, the principal inquiries being from Russian and San Francisco dealers. American business moving slowly, and orders below the average. Manufacturers are reluctant to book orders at present prices, and the market is reported as firmer at the iron masters' quarterly meeting held in Birmingham, the week before last. Some large shipments, amounting to 122,797 boxes, had been made from Swansea.

IMPORTS OF TIN into Great Britain during the first half of this year were 339,456 hundredweight, against 274,957 hundredweight in 1892, and 337,836 in 1891. The value of pig tin received was $7,484,098. Of this amount 607 hundredweight was shipped again to the United States.

THE STRIKE at the Carmarthen Tin-plate Works, Carmarthen, Wales, is reported as raised and work has been resumed after a stoppage of nine weeks. Mutual concessions were made by employers and employed in the matters under dispute. The struggle was carried on with the greatest good feeling on both sides. Gilbertson's Pontardawe tin-house men are still out on strike.

N. & G. TAYLOR COMPANY continue to make a good showing at their tin-plate works in Philadelphia. The following figures, furnished by the firm exhibit their output of tin and terne plates for the six months ending June 30:

	Net weight. Pounds.
Tin plates lighter than 50 pounds per 100 square feet	1,190,738
Tin plates weighing 50 pounds per 100 squre feet	691,226
Tin plates weighing 62½ pounds per 100 square feet	105,117
Tin plates weighing 63 pounds per 100 square feet and heaver	503,301
Terne plates lighter than 50 pounds per 100 square feet	1,753,383
Terne plates weighing 50 pounds per 100 square feet	1,656,946½
Terne plates weighing 62½ pounds per 100 square feet	54,641
Terne plates weighing 63 pounds per 100 square feet and heavier	333,902½
Total	6,289,255

VALUABLE TESTIMONY is constantly coming to hand respecting the quality of American tin plate. Among the warmest advocates of the new material are country tinsmiths, who have put it to test with satisfactory results. Not long ago in conversation with a dealer in the country districts he announced that he ordered American tin plate every time, and in the cheaper grades he considered them far ahead of the imported article. There was not, however, so much difference in the higher-priced plates.

A BRIGHT, smiling young man and one who is popular with the tinners and consumers of solder, tin plate and registers is J. Rudderow, though 22 years have been passed in attending their wants in the service of Hall & Carpenter of Philadelphia.

IN RESPECT of the tin-mining industry of the Black Hills in South Dakota, the *Hill City Tin Miner* observes as follows: "It may perhaps not be generally believed, owing to certain recent unaccountably peculiar workings of the parties principally in interest, that there are in the southern hills extensive bodies of tin ore which can and will, perhaps sometime in the dim future, be profitably mined and worked; but such is nevertheless the case, and these bodies of ore do not by any means all belong to corporation capital. While possibly a long time may elapse and larger capital be required in the development of these mines than in those of the gold belt, it is none the less true that, despite the reasonable doubt of their existence on the part of the investing public, they are good property to own."

TIN-PLATE IMPORTATIONS for the first four months of this year were 90,770 gross tons. This shows a falling off of 3398 tons from the figures for the corresponding period of 1892; while consumption has increased.

TIN PLATE in transit from Great Britain to West Indies, Central and South American ports, via New York, amounted to but 1680 pounds for June, 1893.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until August 9, for all the labor and materials required for the excavation, concrete foundations, cut stone and brick work, iron and wood floor, ceiling and roof construction, roof covering, drainage, approaches, &c., for the United States post office building at Staunton, Va., in accordance with the drawings and specification, copies of which may be had at the office of the Supervising Architect, Washington, or from the superintendent, at Staunton, Va.

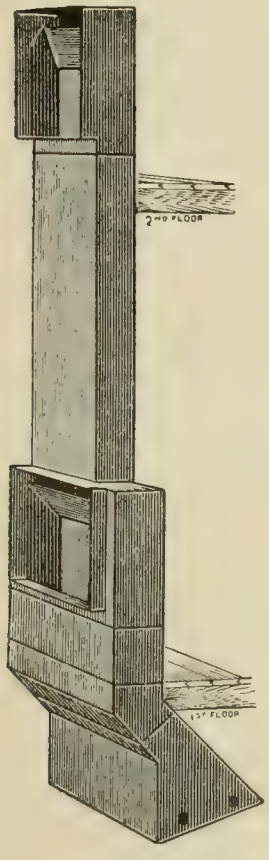

Fig. 1.—Stack of Novelty Ventilated Wall Pipe.

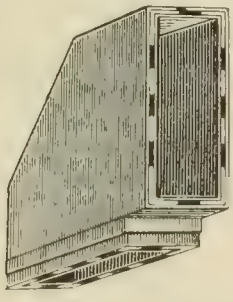

Fig. 4.—Right Angle One-Piece Edgeway Ell.

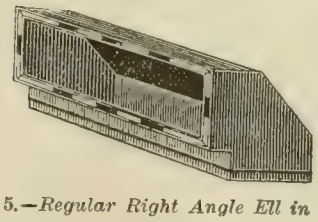

Fig. 5.—Regular Right Angle Ell in One Piece.

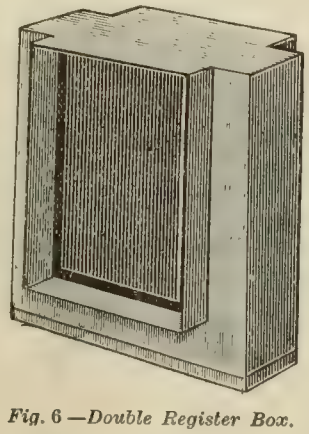

Fig. 6.—Double Register Box.

NOVELTY VENTILATED WALL PIPE.

Patents have recently been granted John P. Schaffer, 18 Wood street, Pittsburgh, Pa., for a new ventilated wall pipe or hot air flue, which he is putting on the market under the name of the Novelty. It is intended for use in the partitions of houses that are to be heated with hot air. It consists of an inner and an outer pipe, with an air space between them to insure safety and guard against the loss of heat. Selected bright tin is used, and the pipe is furnished in lengths of 8 feet with a complete line of fittings to facilitate its erection in a building. Shorter lengths are furnished when ordered, but a feature of the pipe is the ease of adjusting the lengths to the requirements. A slip socket connection fits on the ends of the pipe and is readily removed to permit the shortening and easily replaced to complete the pipe. It is stated that this work can be done with facility at the building where the pipe is being erected, while the long lengths securely double seamed together effect an appreciable saving of time and labor. Fig. 1 shows a 45° foot piece to receive the pipe from the furnace connecting with a 45° ell, making an offset to clear a timber, then connecting with a short piece of pipe with a register box, from the top of which a smaller size of pipe runs to a room above. Fig. 2 shows a right angle foot piece. Fig. 3 is two 45° edgeway ells for making either a right or left offset, or a right angle ell. Fig. 4 is a right angle edgeway ell in one piece. Fig. 5 is a regular right angle ell in one piece, and Fig. 6 is a double register box. The ease with which these fittings connect and the varied requirements they meet has, we understand, been satisfactorily demonstrated in some of the fine residences in Pittsburgh during the past winter. Being made of special sizes of tin and by machinery there is no waste of material. In sizes the inside or air-carrying pipes are 3 x 7¼, 3 x 9¼, 3 x 11¼, 3 x 13¼, 4¼ x 11¼, 4¼ x 13¼ and 11¼ x 11¼, with all of the various fittings for each size. The outside pipe is ¾ inch larger in dimension, and the air space is made to connect from the base of the pipe to the register.

The *Mineral Water Review* gives the following reasons why tinned vessels exposed to the action of mineral waters are apt to rust: "Pure tin is not affected at ordinary temperatures, but as soon as a portion of the tin is removed by injury so as to expose even a tiny speck of iron surface, corrosion at once sets in and proceeds very rapidly. The reason of this is of an electrical nature—that is, iron and tin together form what is called a "galvanic couple," which will decompose the water charged with carbonic acid deposited upon them from the air; oxygen and hydrogen gases are liberated, and the iron, having the greater affinity for the oxygen, is the metal attacked, in particular, such corrosion is very rapid when the exposed iron surface comes in contact with water highly charged with carbonic acid, as in a mineral water factory.

THE LETTER BOX.

A Day's Work in Tin Roofing.

From C. R., *Spokane, Wash.*—Kindly state through the columns of *The Metal Worker* the average number of squares of tin roofing (20 x 28 inch tin) a practical roofer can finish in one day's work of ten hours.

Note.—From statements of practical roofers on this question it appears that to lay, nail down and solder from three to four squares of 20 x 28 inch tin roofing on straight work is considered a fair day's work of ten hours for an average man. This is on flat seam roofing, for which the sheets have previously been matched and locks turned. For standing seam roofing the average is from five to six squares for ten hours' work. The tin is put down in strips, which are cut from rolls of tin put together and soldered in the shop. The workman has to turn the locks, cleat down the strips, make the standing seam and do whatever soldering is required to make this amount of roof surface tight. This does not include any extra fitting, flashing, coping, &c., but is for straight work only. There are many tinners and roofers who will be able to do a greater amount of work than the estimates given. There are also a great number of workmen who would not be able to accomplish the amount of work set as the average standard, though the quality of their work would be their recommendation. The difference between the time considered sufficient to do any job of roofing and the time it actually required depends on how the men are managed, and how the work is handled by foreman, as well as on the efficiency and willingness of the workmen.

Core Box Plane.

From PATTERN MAKER, *New York.*—The article of "R. A. F.," on core box plane attracted my attention, as I have been using just such a tool of my own make for many years. He says he never saw any except those made by the owners, but I have also one manufactured by Collins & Rice of Cleveland, Ohio, that is made of cast iron with extension sides for cutting large core boxes. My old plane is the favorite for small work, owing to its lightness, and, furthermore, a wooden plane does not wear the sides of the work like the end of an iron plane.

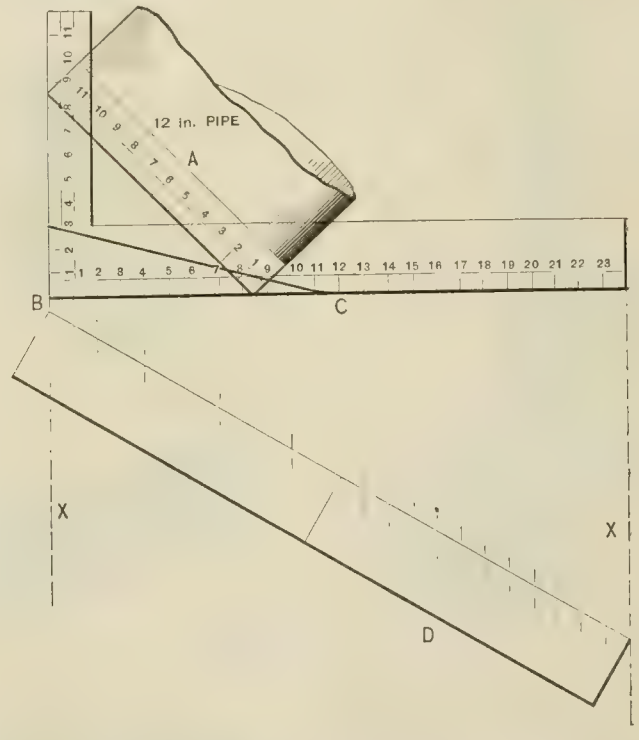
Gasoline Burner for Hot-Water Boiler.

From R. L. S., *Fredericksburg, Va* — I have a customer who has a hot-water heater for warming a house. The house is not a large one and he wants to use a gasoline burnner to heat the water, as he thinks it would be cheaper than coal. I wish to know where I can get such an arrangement and what would be the best way to connect it.

Note.—We do not know of house-heating boilers heated with gasoline fuel attachment, but if any of our readers have had experience in this line, or have any ideas to suggest, we should be glad to hear from them.

Circles and the Shop Square.

From H. W. W., *New York.*—I have observed from time to time in *The Metal Worker* during the last few months graphic methods for computing the circumference of a circle with a right angled triangle, or an ordinary square. It calls to my mind some calculations I have seen demonstrated with the square and rule, for example: The rule A, Fig. 1, is just 12 inches long and represents a pipe 12 inches in diameter. We will assume that there are two branches or pipes to be taken from the 12-inch main. What must the diameters of the branches be to equal the capacity of the main? By referring to Fig. 1 it will be observed that the rule A is 8½ inches from B on the base C, and 8½ inches from B on the perpendicular, which shows that two 8½-inch pipes must be used to equal the capacity of the 12-inch main. Again, suppose we had a 3-inch pipe already in what diameter will the other be. Place the rule A at 3 inches on the perpendicular shown by the single line, the other end will reach 11⅝ inches on the base C, which shows that a pipe 11⅝ inches in diameter must be used with the 3-inch to equal the 12-inch pipe; and in a like manner when one diameter is given it will give the other two, or when two diameters are given it will show the third. I saw, while finishing this sketch, a method of dividing a piece of any material into equal parts, which is shown and explained, without interfering or complicating the first explanation. In this case we have a piece that may represent a sheet of metal, a pipe, or anything else, 30 inches long, which it is desired to divide into 24 equal parts. Place it in an oblique angle so that both upper corners will bisect the lines X X in Fig. 1, which equals the 24 divisions.



Circles and the Shop Square.—Fig. 1.—Find the Diameter of Two Circles Having Area Equal to that of a Larger Diameter.

Fig. 2.—A Circle Inscribed within a Square whose Sides Equal its Diameter.

While discussing this subject to areas and circumferences of circles a good opportunity is offered to say a word by way of explanation of the arithmetical rules for computing the areas and circumferences of circles. All circles are to each other as the squares of their diameters, and these multiplied by the decimal 0.7854 give their area. The diameter of a circle multiplied by 3.1416 equals its circumference. To make the above statement plainer and more comprehensive I have made the sketch shown in Fig. 2. All its sides are equal, its angles right angles, and contains one square inch. The inscribed circle is one inch in di-

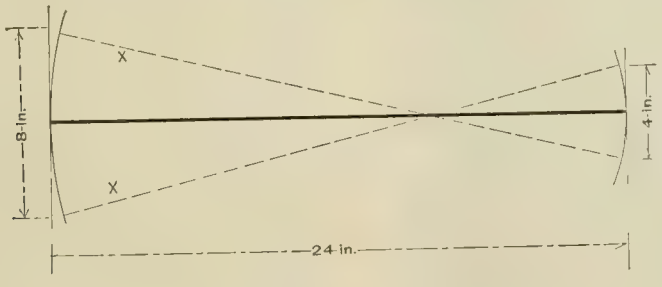
ameter. Although it is one inch in diameter, it contains only 0.7854 square inch, as shown by the shaded part. We will substract the circle from the square, representing the square by 1.000 — 0.7854 = 0.2146. Here we have the area of the three spaces, the square 1., the circle 0.7854 and the shaded part 0.2146.

Locating a Fulcrum.

From H. W. W., *New York.*—A handy way of locating a fulcrum on a lever is as follows: Divide the length of the lever by the sum of the two sweeps and multiply the result by one of the sweeps, which will give the distance the fulcrum must be placed from the sweep used. Suppose we have a lever 24 inches long and it has a sweep of 8 inches at one end, where must the fulcrum be located to give a sweep of 4 inches at the other end?

8 + 4 = 12, the sum of the sweeps.
24 ÷ 12 = 2, the result of dividing the length of the lever by the sum of the sweeps.
2 × 4 = 8, the result multiplied by the smaller sweep, giving the distance the fulcrum must be placed from it.

The cut shows the graphic method, which is to lay off the length of the lever, full size or to a scale, if you wish; also the given and the desired



Locating a Fulcrum.

sweep; then draw the diagonal lines X and X and where they bisect will be the point of location. Still another way of making this calculation is by the old-fashioned single rule of three, or proportion. As the sum of the sweeps is to the length of the lever, so is the length of either sweep to the distance the fulcrum must be placed from it on the lever. As 12 is to 24 so is 4 to the distance the lever must be located from it. The distance is determined by multiplying the means and dividing by the extreme 24 × 4 = 96 ÷ 12 = 8 inches, the distance the fulcrum must be placed on the lever from the end having the 4-inch sweep.

Heating Range Boilers.

From H. W. W., *New York.*—In reply to the inquiry of "J. H. B.," that appeared in *The Metal Worker* of July 15, would say that the heater A would circulate or heat the greater quantity of water, for this reason: Although the uptake tube of B is 8 inches higher it has less pressure, on account of the 8-inch column of water resisting its circulation; while, on the other hand, it has 8 inches more pipe on the uptake and about 2 inches more pipe to the supply. As the water backs are an equal distance from the tanks, the pipe B will have the shorter bends, and the shorter bends, together with the tortuous passage of the water through 10 inches of pipe, will be an impediment to circulation. There is also more surface in the pipe B exposed for the radiation of heat. These features would seem to overcome any advantage it would gain from the higher connection. To determine which of these tanks would circulate the quicker would, in my judgment, require a very careful test under the following conditions: Both tanks to be tested with the same water back and same range, coal, draft, &c., for the conditions of the two tanks are so nearly alike that to test them with separate water backs and ranges would leave the question as to which is the better undecided. It takes but a very small impediment to affect the free circulation of water in pipes by the application of heat. The particles of water absorb the heat from the iron, become expanded and are forced upward by other particles of greater density falling in their place by gravity. It is easy to appreciate, therefore, what a small obstruction would check the motion of this water. It is these obstructions that determine to a great extent the quantity of water that can be heated in a given time. It will be seen that if the better circulator of the two had any of these defects the poorer one would give the better results and we would still be in ignorance as to which embodied the more correct principle.

Flat Seam Roofing.

From WILLIAM SURRELL, *New Madison, Mo.*—I do not fully understand how "J. H." of Harrisburgh, Pa. lays his flat seam roofing, an account of which was presented in a recent issue of *The Metal Worker*, and I would be very glad to have him send me a finished sample.

Trouble with Water Back.

From F. M. P., *Washington, N. J.*—I would suggest to J. P. & S., Haddonfield, N. J., that perhaps they will find a partial stoppage either in the water back or pipes connected therewith. I trust that they will give a full report of the way in which they remedy the difficulty.

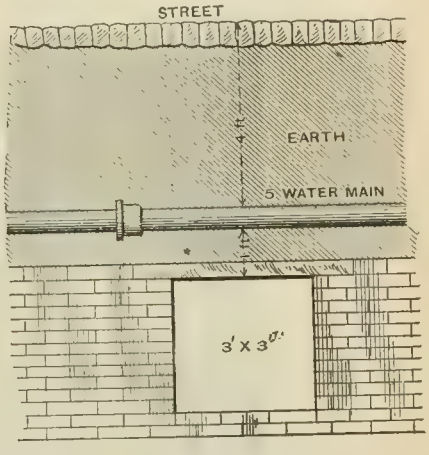
From C. B. T., *Shamokin, Pa.*—In *The Metal Worker* of July 15 is a letter from "J. P. & S.," Haddonfield, N. J., in reference to trouble with a water back. I once had an experience of the same kind, and found that the boiler was too large for the capacity of the water back. I would advise the correspondents to try a smaller boiler or two water backs.

From J. W., *Wappinger's Falls, N. Y.*—In reply to your correspondent "J. P. & S.," who write concerning their trouble with a water back, I would advise them to look at their hot-water pipe. I had similar trouble with a water back, and after much bother, found that the hot-water pipe was leaking.

Water Main Near Culvert.

From A. & M., *Tidioute, Pa.*—We send herewith sketch of a 5-inch water main on which we would like your advice in regard to the danger of its freezing. The pipe is to be buried 4 feet deep, and would lie but 1 foot above a stone culvert. How and what way would be the best to protect it from the frost coming up from below. Would you advise running the pipe below the culvert, which would then make it a depth of 10 feet from the surface?

Answer.—Of course the latter suggestion of our correspondent would be the most effective, and there would be no danger of the pipe freezing if put so far beneath the surface of the ground. Nevertheless, we think it would be needless expense and trouble to sink the main so deep. As a matter



Water Main Near Culvert.

of fact, while the culvert gives opportunity for freezing it is not to be presumed that the frost will enter on the sides of the culvert to any such depth as it would from the surface of the ground. The particular conditions will govern this matter very largely. For instance, we do not know whether the culvert is in the line of the cold winds, how long it is, whether curved or straight, all of which will govern the depth of frost from the sides and top. Unless it is in a particularly exposed place and in a very cold locality we think that a packing around the water main where it crosses over the culvert would prevent its freezing. Any of the well-known insulating materials could be used, preferably inside of a box, through which the pipe was run for a few feet over the culvert. A box 1 foot or 18 inches in size, packed full of a good insulating material, ought to be sufficient protection against frost in this one spot.

Hardening Sheet Brass.

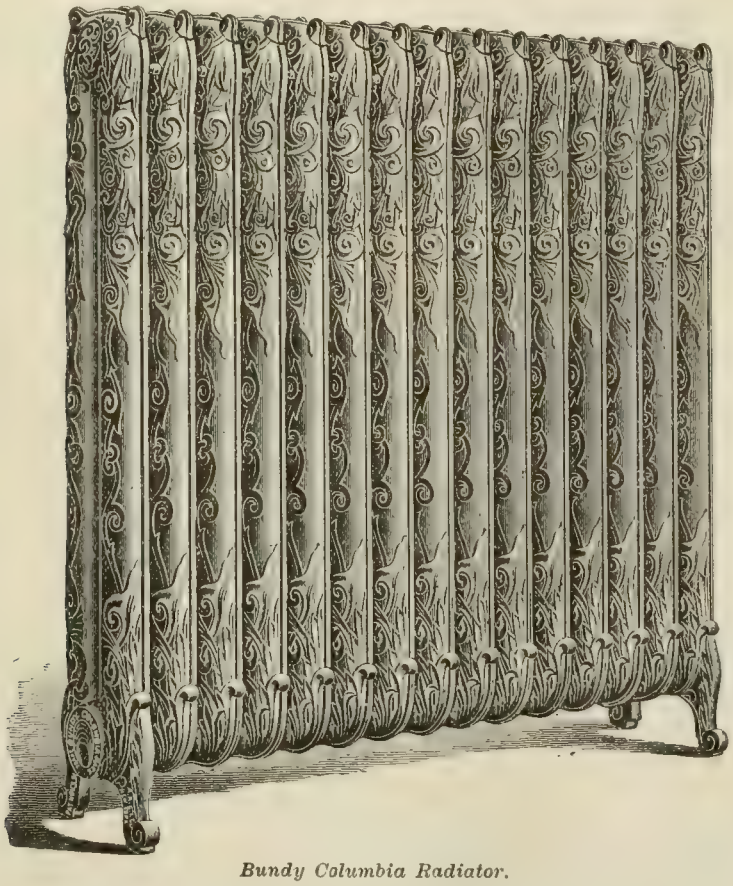
From C. O. L., *Brooklyn, N. Y.*—Please inform me how I can harden sheet brass after the same has been bent into shape?

Hon. Patrick Walsh of the Augusta *Chronicle* says that three things are necessary to make the South prosperous and independent—namely, diversified agriculture, the pursuit of mining, and the development of manufactures.

STEAM AND HOT WATER.

The Bundy Columbia Radiator.

The accompanying illustration shows a general view of the Bundy Columbia Radiator, which has just been put on the market by the A. A. Griffing Iron Company of Jersey City, N. J. The style of decoration they describe as Byzantine, tracing the general form of the figures back to the early centuries when this type of architecture prevailed. The firm inform us that the radiator was brought out in commemoration of the Columbian Exposition, where it is exhibited among their goods in Section O, Block 3, of the Manufactures and Liberal Arts Building. The radiator is made for both steam and hot water, in five hights from 45 to 20 inches, and is adapted to fit corners of rooms, bay windows, circles, columns, staircases or windows. The Radiator is put together with screw threaded nipples at the top and bottom, no packing or gaskets being used in its construction. A noticeable feature to which the manufacturers refer is the fact that the bottom and top of each section is enlarged, improving the appearance and furnishing a broad stand at the top upon which objects may be placed. The 45-inch radiators contain 5 square feet of heating surface per section and the 20-inch 2 square feet of heating surface per section.



Bundy Columbia Radiator.

HEATING NOTES.

W. M. MACKAY, the well-known heating engineer, has resigned his position as manager of the school and public buiding heating and ventilating department of the American Boiler Company to accept the management of the steam and hot water department of Hart & Crouse, manufacturers of the Royal Heaters. Mr. Mackay's headquarters will be at 236 Water street, New York, on and after August 1, where he will be pleased to see his many friends in the heating trade. He is now on a visit to the World's Fair at Chicago.

THE DEALERS in steam, hot air and hot water apparatus in Newark, N. J., recently had the pleasure of a visit from two genial business men from New York—L J. Parks, representing the Richardson & Boynton Company, and Geo. W. Plastow, representing the American Boiler Company.

A CIRCULAR with a very old-fashioned flavor to it comes to us from the Mason Regulator Company, 10 Central street, Boston, Mass. The publication, which is a folded card, is a similitude of a ribbon-bound note. The printed address is gotten up in true antique style and conveys instructions to the postman to carry it with the greatest speed. Within there is similar quaint reference to the Mason Regulator Company and their wares.

THE HOLLAND RADIATOR COMPANY of Chicago have sold 200,000 feet of the product of their Bremen plant to the J. L. Mott Iron Works.

THE THEO. JACOBS COMPANY, 72-74 Market street, Chicago, have taken the contract for the heating and power plant in the new Y. M. C. A. Building, 155-157 La Salle street. A 500 horsepower Heine safety boiler will be used in connection with 18,000 feet of radiation. The above firm are also to overhaul the heating plant in the Savoy Hotel, Michigan avenue, near Twelfth street. This plant was put in some two years ago by parties who are now out of business.

THE L. H. PRENTICE COMPANY, 203 and 205 Van Buren street, Chicago, have taken the contract for supplying six boilers, pumps, tanks, &c., for the heating and power plant in the old and new buildings of Mercy Hospital, Twenty-sixth street and Calumet avenue. The above firm are also to furnish the heating and power plant in the Greunewald Building, New Orleans.

A PAMPHLET DESCRIPTIVE of the Richmond heaters for steam and hot water, manufactured by the Richmond Stove Company of Norwich, Conn., is issued by Allen Black of St. Paul, Minn., and also in the interests of the two other firms of Allen Black & Co. of Duluth, Minn., and Black, Spriggs & Co., Grand Forks, N. D. The pamphlet of 20 odd pages is neatly bound in colored paper with gilt lettering. The inner pages of fine paper contain illustrations of the various Richmond heaters, both general and sectional views being presented. Brief particulars of the apparatus are given and tables of sizes, capacities and prices are likewise printed. At the close of the pamphlet are testimonial letters and a list of those using the Richmond heaters in the West.

THE THAYER HEATER COMPANY of 134 High street, Boston, Mass., distribute a neatly illustrated circular respecting their hot-water heater. The pamphlet, which is well published, consists principally of testimonial letters received from the various users of this apparatus. On the front page of the publication is a broken view of the Thayer heater, followed by some general remarks on the apparatus and hot-water heating. Then come testimonial letters and, later, a long list of some of their patrons, and this in turn is followed by a table of sizes, capacities, &c., and then come further illustrations of heaters, unions, special fittings, &c. Another publication issued by the same concern is a little black-covered pamphlet, entitled "Directions for Setting up the Thayer Hot-Water Heating Apparatus." This is a neat and serviceable little book, and will be distributed on application. It begins with some remarks on chimneys, the general arrangement of piping, sizes and capacities of heaters, &c.; then comes information about piping and sizes, as well as the radiating surface to be used.

THE UNITED STATES RADIATOR COMPANY of Loyalhanna, Pa., have been granted a charter with a capital stock of $50,000. The directors are G. C. Blackmore, New York City; D. L. Sloan, C. C. Elwood and C. F. Crawford of Pittsburgh; H. M. Mechling, James A. Shields and Nathan Miles of Greensburg.

ROOFING AND CORNICE.

Condensation Gutters on the Inside of Windows.

From W. N., *New York.*—In furnishing the roofing and cornice work for churches the specifications usually call for condensation gutters on all chapel and dormer windows. For the benefit of sheet-metal workers who may be called upon to do this class of work I think the following will prove interesting.

It is a well-known fact that warm air will rise upward, and when coming in contact with a cold surface, such as glass, for instance, the glass begins to sweat on the side having the warm air, an example of which can be seen in our dwellings during the winter months, thereby causing not a little moisture to accumulate.

Such was the case with a church I have in mind, the church being heated day and night, and all windows and ventilators tightly closed in cold weather. The chapel and dormer windows began to sweat continually, thereby causing the moisture to run down the wooden sill on the inside and ruin the frescoed walls. To overcome this a sheet-metal gutter was placed on the inside of each window, connected to a metal tube, which conveyed the condensed moisture to the outside. The descriptions and the diagrams herewith will show how the work was done. In Fig. 1 is shown the front elevation of a wooden or metal dormer window on a pitched roof, the roof covering being either slate, shingles, flat or standing seam tin roof. A and B represent the flashing around the sill of the dormer, which is soldered and riveted water-tight to the dormer in the shop, and is slated in with the the courses in case the roof was of slate or shingle. X represents the outlet of the tube, which is connected to the gutter on the inside. The glass in the wooden sash is shown in Fig. 1. Fig. 2 represents a sectional view on line C D in Fig. 1, and shows the rafter, Y Y, on which the roof

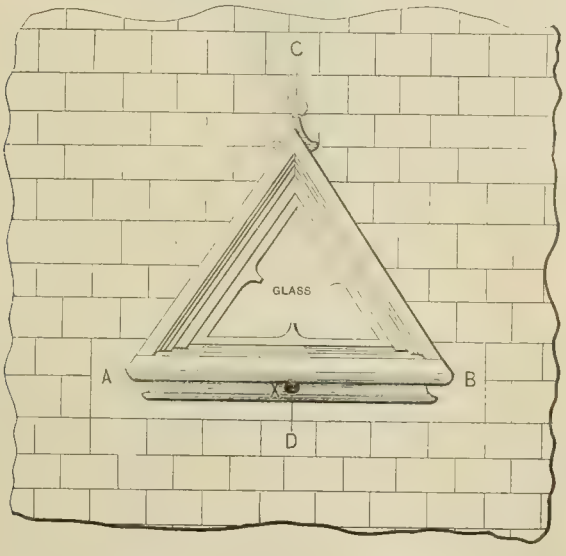


Fig. 1.—Front Elevation of a Dormer Window on a Pitched Roof.

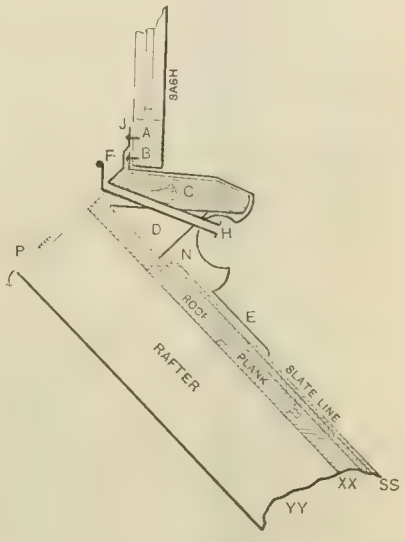

Fig. 3.—Enlarged View, Showing Fastening of Gutter in Fig. 2.

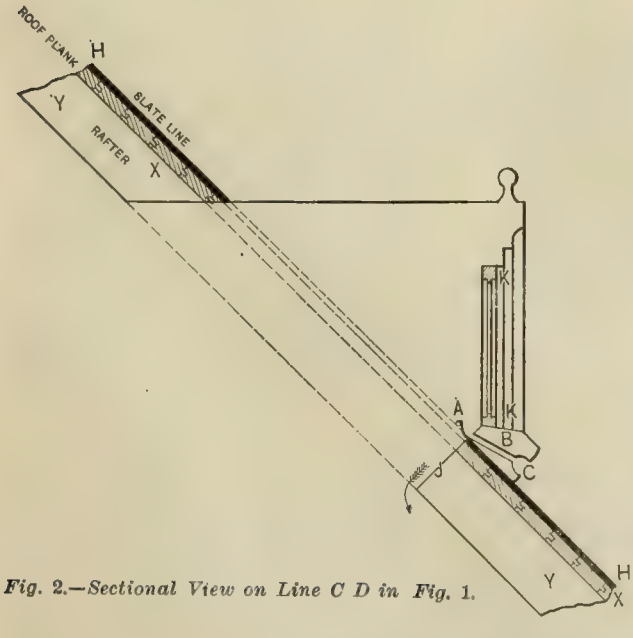

Fig. 2.—Sectional View on Line C D in Fig. 1.

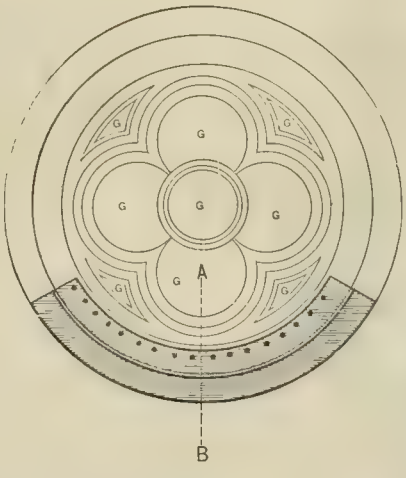

Fig. 4.—Inside Elevation of Circular Window, Showing Condensation Gutter in Position.

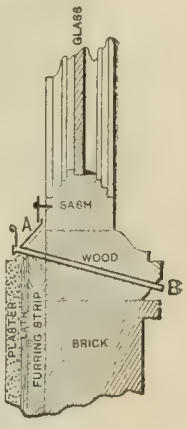

Fig. 5.—Sectional View through A B in Fig. 4.

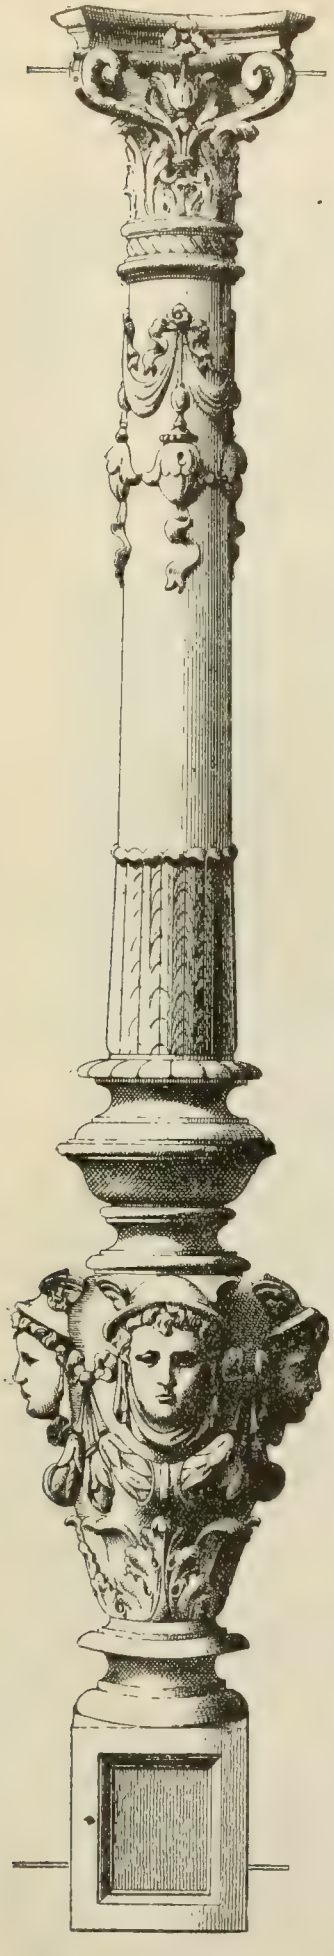
CONDENSATION GUTTERS ON THE INSIDE OF WINDOWS.



Sheet Metal Covering for Iron Column.—Fig. 1.—Casing Complete.

boards, X X, are nailed, the slates being shown by H H. In this case the dormer was made of sheet metal and the wooden sash, shown by K K in Fig. 2, was placed in last, or after the dormer was set. The moisture dripping from the glass in the sash K K would follow the arrow J and drip inside of the building. A gutter was placed as shown at A, being nailed against the sash K. A tube in the center of the gutter was placed as shown at X in Fig. 1, and passing through the sill B projected over the cove molding C, as shown in Fig. 2. Fig. 3 is an enlarged view of part of Fig. 2, showing the manner of fastening the condensation gutter. Y Y represent the rafter, X X the roof planks and S S the slates. D is a wooden bracket nailed to the roof planks, on top of which the wooden sill C is placed. If the roof is of slate, after slating up as far as N, the metal dormer, with the flashing attached around and water-tight to the sill, as shown by A B in Fig. 1, is placed over the wooden sill C and over the slates, as shown in Fig. 3. After the dormer is framed on the inside by the carpenter the wooden sash shown in Fig. 3 is placed into the metal dormer from the outside, against the flange bent up on the metal sill, and nailed as shown at B. This flange prevents the rain, when striking against the dormer, from running or soaking to the inside, as was first supposed to be the case, before the condensed moisture was thought of. The sash being fastened the condensation gutter is formed corresponding to the shape of the inside sill, as shown by F J in Fig. 3. The length being obtained a head is soldered at each end and a hole punched in the center of the gutter, and at its deepest point, corresponding in size to the tube used, which is usually ¾ inch diameter. A wired edge is placed at the top of the gutter, as shown at F. The gutter is placed temporarily in its proper position and a mark made where the tube will pass through the wooden sill C. Then, taking away the gutter, bore a hole through the wooden sill C with an auger, and, using a small sharp chisel and hammer, cut a round hole through the metal sill, as shown at H. Set the gutter again in its proper position, placing a bedding of white lead between the upper flange J of the gutter and the bottom of the sash. The flange J is nailed every ½ inch with small tinned tacks, thereby making a good water-tight joint. The metal tube is now placed through the hole in the metal sill H and through the wooden sill C, from the outside, until it projects about ½ inch over the inside of the gutter; then with a small hammer a flange is turned on the tube and against the gutter, and soldered water tight, which completes the job.

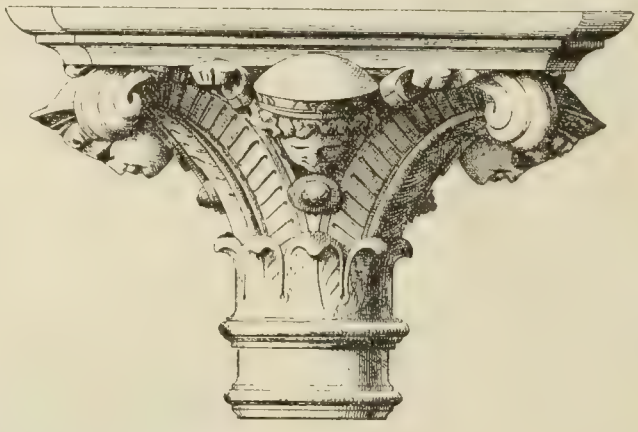


Fig. 2.—Capital for Casing.

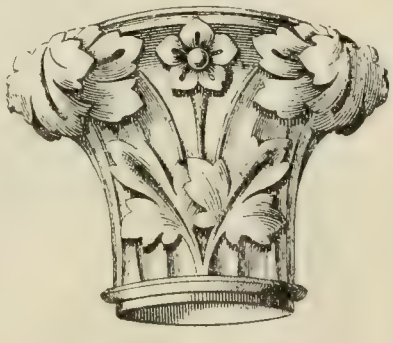

Fig. 3.—Capital for Casing.

The same method, shown in Fig. 3, would be employed on the chapel windows, with the exception that the latter are usually all made of wood. The writer has in mind a condensation gutter which was made for a circular window, 8 feet in diameter, over a choir in a church in Yonkers, N. Y. The gutter was made to correspond to one-third of the circle, as shown by the heavy lines in Fig. 4, and nailed along the edge of the sash, as shown, using white lead, as before explained, to obtain a water-tight joint. G G G, &c., in Fig. 4, indicate the glass. The method used to fasten the gutter and to connect the tube is the same as shown and described in connection with Fig. 3. Fig. 5 is a sectional view, taken on the line A B in Fig. 4, and shows the method of flanging the bottom of the gutter at A. The tube is shown at B. Care should be taken to solder water tight and heavily the two upright strips of the gutter to the bottom, shown at A in Fig. 5.

Sheet-Metal Coverings for Iron Columns.

Fred F. Bischoff & Co., 24 and 26 West Lake street, Chicago, are manufacturing a line of sheet-metal column coverings, Fig. 1, and capitals, Figs. 2 and 3, for decorating iron columns, illustrations of some of which are herewith shown. These articles are made of zinc or copper and in such lengths and sizes as may be required. For convenience in placing them about iron columns after they are in position, the coverings can be constructed in halves, the necessary joints being made by soldering. The space between the covering and the column can be filled with sand or plaster of paris, thus securing fire protection. The increasing use of iron and steel construction is furnishing an excellent field for work of this character.

FLASHINGS.

THE ACME ROOFING COMPANY, Canton, Ohio, are building, a two-story office building, 20 x 28 feet, the indispensable business correspondent, bookkeeper and their help having been gradually crowded out by the growth of their business. With all the necessary machinery for making steel roofing and corrugated, beaded, pressed brick and weather-board siding and cornices, cresting, finials, conductor and some new things in eave troughs, no doubt the additional space gained in the shop when the office moves to the new building will prove highly useful.

THE NEW MANUFACTURING BUILDING of the Canton Steel Roofing Company of Canton, Ohio, is full of busy workers turning out steel roofing, coated with their anti-rust graphite paint, and all of their specialties, though new machinery that is on the floor is yet to be put in operation and the office and paint house yet to be built. The promptness of getting in running order after being burned out is only a sample of the energy that is infused into their business.

THE BERGER MFG. COMPANY, Canton, Ohio, expect soon to be in the new plant they have been building about a mile down the railroad from their present location. It is arranged to save handling and to pass the raw material from department to department till it reaches the storehouse or cars completed. The main building is 60 x 600 feet, and here the machinery is located and manufacturing done. On both sides of this building is a railroad switch for receiving tons of tin plate and steel and shipping cars of goods. Across the switch and beside the main building is a pressroom 40 x 50 feet and a paint and storage building 40 x 270 feet. All of these structures are one story, of ample hight, and well provided with windows for light and air. At the end of the main building is a three-story brick building 35 x 70 feet, which will be used for offices and for drafting and designing rooms. In the new plant steel roofing in all its forms, steel and copper siding in some novel styles, ceilings, cornices, finials and all of the many specialties of the company will be turned out under advantages not previously possessed.

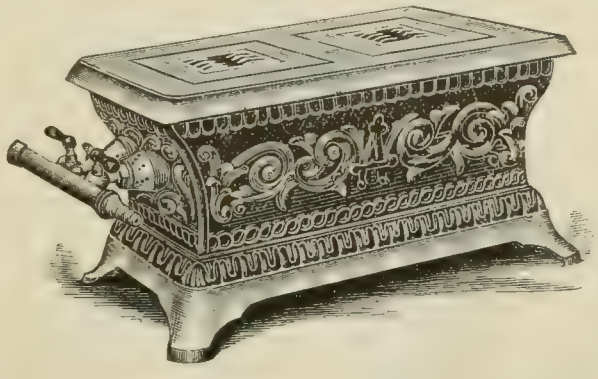
ADVICES from the West report a brisk demand for roofing materials, as many building operations are nearing completion. Tin plates, copper and other lines used for this purpose are being circulated in heavy shipments, prices being firm.

M. HARRISON & SON, 214 and 216 East Fifty-second street, New York, have a large well-lighted shop, provided with all essential tools and machines for turning out cornices, skylights, ventilators, gutters and builders' sheet-metal work.

PROMINENT AMONG the varied products of the Newark Sheet Metal Ware Company, Newark, N. J., is plain and corrugated galvanized leader. A new machine has recently been made for them by Ohl & Haefner of the same city, which turns out an 8-foot length in 40 seconds. A galvanizing plant is now being erected, when the leader will be made of black iron and afterward galvanized. Sheet-metal railway supplies are manufactured for many of the principal railroads, each requiring special sizes and shapes suited to their rolling stock. Valves and plungers for sheet-metal pumps are other lines that are sold to widely separated ship chandlers and pump makers. Some specialties are made in stamped and pieced tinware, for bakers' and confectioners' use. Their showcase contains some fine samples of brass and copper goods, in funnels, measures, coal hods and confectioners' trays.

The Fire King Water Heater.

A. Weiskittel & Son, Baltimore, Md., have placed upon the market a new gas water heater which is shown in general view in the accompanying engraving. In putting in a heater of this kind, where a range water back and circulating boiler are already in use, the makers state it is only necessary to cut the circulating pipes and insert two tees to connect with the gas water back. By this arrangement hot water can be obtained from the boiler whenever either of the water backs are in use. The exterior of the Fire King water heater here shown is made of ornamental cast iron, while the water generator itself is made of cast brass. Two powerful burners are provided running the entire length of the water back and when both are in operation it is stated that a 30-gallon boiler can be heated to about 95° in half an hour. When the water in the boiler is heated to the desired temperature, one of the burners can be extinguished and the flame of the other turned down so as to generate only a sufficient amount of heat to keep the water hot. The water heater is provided with two boiler holes in the top so that cooking operations may be carried on at the same time the water is being heated if so desired.



The Fire King Water Heater.

What's in a Name?

It is said that the London publishers of Rudyard Kipling's new collection of short tales under the title of "Many Inventions," have received inquiries respecting the work from representatives of more than one trade and technical journal, who were evidently under the impression that it contained a record of novel devices, mechanical or otherwise. When Horne Tooke's "Diversions of Purley," an abstruse philological work, was reprinted a few years ago, it was ordered by numerous circulating libraries in the expectation that it would be found to be light literature of a diverting kind. Similarly Ruskin's books have, it is said, frequently misled folks by their erratic titles. For instance his "Treatise on Sheepfolds" has been repeatedly in request by bucolic individuals anxious for information about the housing of sheep. They are generally disappointed on finding that the book is a theological essay. The same author's "Sesame and Lilies" has been sometimes catalogued among horticultural works.

Flimsy Kerosene Cans.

In a recent report to the State Department U. S. Consul Plumacher, at Maracaibo, complains of the careless packing of American kerosene received by importers at that place. In every consignment recently received there is said to have been much loss by leakage, notwithstanding the most careful storage and handling. Desiring to reduce as much as possible the gross weight, upon which duties are levied in Venezuela, American shippers of this oil have gone to extremes. The kerosene is packed in tins of 5 gallons each, two of them being stowed in a tight-fitting wooden box. The tin now in use is much too thin, and the wooden boxes are of light material fastened by too few nails. The result is that many tins arrive empty and others require resoldering, while the boxes are practically in pieces. A great proportion of the kerosene does not remain in Maracaibo for consumption, but is sent to various points in the interior of both Venezuela and Colombia. Before this can be done both tins and boxes must be thoroughly repaired, which expensive process may have to be repeated several times before the oil arrives at its final destination, thus increasing its cost. Moreover the leaking oil is liable to damage other cargo.

Consul Plumacher strongly recommends the use of a heavier and more carefully soldered tin for the inside cases of kerosene.

The wealthiest nation on the globe, according to an exchange, is the United States, which has an assessed value of $47,475,000,000; next coming Great Britain with $43,600,000,000; France ranks third with $40,300,000,000; then Germany with $31,600,000,000; Russia comes next with $21,715,000,000; Austria follows with $18,065,000,000, and Italy succeeds with $11,755,000,000; Spain is worth $7,965,000,000; the Netherlands, $4,935,000,000; Belgium, $4,030,000,000. The assessed valuation of Sweden is $3,475,000,000; of Canada, $3,250,000,000; of Mexico, $3,150,000,000; of Australia, $2,950,000,000; of Portugal, $1,855,000,000; of Denmark, $1,830,000,000; of the Argentine Confederation, $1,660,000,000; of Switzerland, $1,620,000,000; of Norway, $1,410,000,000; of Greece, $1,055,000,000.

PLUMBING and GAS FITTING.

New Mercury Gauge.

A. Y. McDonald Company, 168 Lake street, Chicago, are putting on the market a new mercury gauge for gas-fitters' use, which is herewith illustrated. Fig. 1 is a general view and Fig. 2 a sectional view. It is 10 inches in length over all. Enough mercury is placed in the chamber to seal the glass tube about ⅜ inch, the cap screwed on, and it is ready for use. The mercury cannot escape, no matter in what position the gauge is placed. It can easily be carried in the pocket.

Fig. 1.—General View of Gauge.

Fig. 2.—Sectional View through Gauge.

New Mercury Gauge.

There is no necessity for removing the mercury except to clean occasionally, which should be done with any gauge.

Massachusetts Plumbing Regulations.

An act for the licensing of plumbers and the supervision of plumbing in Massachusetts has just been passed into law by the State legislature. Its enactments are briefly as follows: 1. No person, firm or corporation not now engaged in the business of plumbing can hereafter engage in or work at the business, either as a master or employing plumber, or as a journeyman, unless he has received a license therefor. 2. Such license to be obtained by application to the Board of Health having jurisdiction in the locality where he intends to work, except in cities and towns where the inspector of buildings has control of the plumbing regulations, in which case the application must be made to such officer, when the application will be referred to the Board of Examiners, by whom the candidate will be examined as to his qualifications. 3. In every city and in each town of 5000 inhabitants or more, having a system of water supply or sewerage, there will be a Board of Examiners, consisting of the chairman of the Board of Health, and where there is such an officer, the inspector of buildings, who will be members *ex-officio* of the board; and a third member, who must be a practical plumber, to be appointed by the Board of Health, and who will hold office for one year. Where there is no inspector of buildings a second practical plumber will take his place on the Examining Board. 4. The Examining Board will designate certain times and places for the examination of all applicants wishing to engage in plumbing within their jurisdiction. If satisfied with the applicant's practical knowledge of plumbing, house drainage and plumbing ventilation, the board will so certify to the Board of Health or inspector of buildings, who will grant the necessary certificate. These licenses will be valid throughout Massachusetts, and be renewable annually upon payment of a fee of 50 cents. 5. The Board of Health or inspector of buildings of each city or town to appoint one or more inspectors of plumbing, who will hold office until removed by the board, their compensation to be paid by the local treasury. The inspectors to inspect all plumbing work for which permits are granted, and report all violations of any regulations regarding plumbing. 6. Each city or town coming under the operation of the act to prescribe rules and regulations for the materials, constructions, alterations and inspection of all pipes, tanks, faucets, valves, and other fixtures by which waste water or sewage is carried. No plumbing work to be done, except in the case of repair of leaks, without permit being first issued. This does not apply to the city of Boston, a special statute law of 1892, governing that city alone, having provided the regulations. 7. The act does not apply to persons who may be learning the business of plumbing until such time as they are sent out to do practical plumbing. 8. Penalties for violating the act are fixed at a fine not to exceed $50, and the license of the offender may be revoked by the examining board.

TRAPS AND VENTS.

"High Grade Lavatories" is the title of a handsome publication just issued by the William S. Cooper Brass Works, Philadelphia, Pa. The pamphlet, 11 x 14 inches in size, contains illustrations of an extensive line of lavatories and lavatory fittings. A special page illustrates Cooper's Porcelain-lined roll rim bath. Twenty-four illustrations are given of the special forms of lavatories, having bowls of various shapes and adapted to different positions. Corner lavatories are shown, while others are for barbers' use and fitted with several bowls. The cuts are neatly executed and all the necessary descriptive particulars are given in connection with them. Later on in the pamphlet are two pages of colored illustrations, showing the appearance of the decorated lavatory basins. At the close of the pamphlet are given sectional illustrations of the Protectus waste, the Security anti-syphon trap, lavatory brackets, faucets, &c.

An International Sanitary Exhibition will be opened at Havre, France, on August 17. The exhibits will include models, plans, material necessary for sanitation of soil, dwellings, cities, institutes, hospitals, &c.

The Bailey-Farrell Mfg. Company, Pittsburgh, Pa., are showing something new in noiseless water closet goods that is interesting and a seat that is fastened to the closet independent of the wall. The latter feature has become in general demand and has several material advantages over a seat that must be fastened to the wall, even though it disfigure handsome tile work and is not substantially rigid.

Geo. L. Simonet recently returned to his old home in West Hoboken, N. J., from Thun, Switzerland, where in the Chartreuse, a hostelry of seventeen rooms, he has been doing the plumbing and gasfitting and erecting a hot-water plant. About 1000 feet of surface of Bundy, Elite and Defiance radiators are used, and a Florida boiler, which was from necessity so set that it is six feet above the radiators on the first floor. One of Terrill's gas machines is used to supply the gas for lighting. The plumbing work comprised every convenience according to the most modern system. After all the work was completed it was submitted to a critical test in operation and a certificate in the possession of Mr. Simonet tells that everything worked in a manner that was in every particular satisfactory. Congratulations on the success of his trip and safe return are received wherever he calls on his friends.

The Goulds Mfg. Company of Seneca Falls, N. Y., have issued a catalogue describing their Duplex water lifters, which have a general application, filling supply tanks in residences, office buildings, &c. They may be employed where the water pressure is insufficient to carry the supply to all points desired, or where the supply is impure, for pumping other water supply from cisterns or other source. The only condition precedent to the successful operation of the Duplex water lifter is a pressure of at least 10 pounds per square inch. The lifter is modeled after the Duplex pump, which, as is well known, consists of two steam pumps of equal dimensions placed side by side and each dependent upon the other for its valve movement. The Duplex lifter, having water-power cylinders in place of the steam cylinders of the steam pump, consists of two pumps of the same dimensions placed side by side, with the valve motion so designed that the movement of the piston of each pump will control the movement of the slide valve of the opposite pump, the effect of which is to allow one piston to proceed to the end of the stroke and gradually come to rest. During the latter part of this movement the opposite piston moves forward in its stroke, and also gradually comes to rest; but in its move-

ment forward and before reaching the end of its stroke the slide valve controlling the first piston is reversed, and in consequence the first piston returns to its original position, and, in nearing the end of its stroke, it in a similar manner reverses the slide valve controlling the second piston. These movements are both uniform and continuous so long as the water is supplied to the power cylinders. This form of valve gear enables the lifter to be run at any desired rate of speed. The catalogue gives full particulars as to the amount of water that can be raised to a given hight with different working pressures, and the amount of water under pressure needed to raise a given supply.

In response to a call from a committee of five to the 150 plumbers in Newark, N. J., and vicinity, a good number attended a meeting on the 27th to form plans to organize a permanent association of master plumbers. Among the objects sought will be the co-operation of the Board of Health in arranging sanitary regulations, a better protection to the trade and the diffusion of the knowledge necessary to the modern plumber. The experience and support of some of the prominent plumbers of New York and Brooklyn has been assured.

The Use of S Traps.

From C. M., *Potsdam, N. Y.*—Please tell me through the columns of *The Metal Worker* the objections to using an S trap to bath, sinks, washbowls and other fixtures on a job of plumbing in a building of two or three stories; also what are the advantages of special forms of patented traps?

Answer.—We do not know of any objection to the use of S traps in the positions named by our correspondent, except, of course, where they are employed without a vent. To simply make an S bend in the waste pipe of the fixture is not adequate protection against the gases of the sewer and drains. A trap of that form is easily syphoned, and there is no certainty whatever that the water will seal it continuously. By the use of a vent pipe—that is, another pipe running from the crown of the trap either into the soil pipe above the highest fixture or else through the roof of the house, the various waste pipes are ventilated and all danger of syphoning the trap is overcome. The special traps to which our correspondent refers have many advocates, and in a general way the claim is made for them that their use obviates the necessity of employing vent pipes. These special traps are so constructed that the seal is not broken by the conditions that would affect the seal in an ordinary unvented S trap.

An ingenious general information machine has, says an Australian exchange, been recently set up in a railway station in Melbourne. By pressing different electric buttons the following, among other things, will appear: A list of the best hotels in the city; a list of the plays at the theaters, with their play bills; a list of the omnibus routes and the cab fares to the various parts of interest, &c. The principle of the machine is capable of infinite expansion, and doubtless we shall soon hear more of it on this side of the Atlantic.

Concerning Heat.

Professor Sells gave a course of lectures in the Old Free Library, Manchester. The conduction and convection of heat were lucidly explained by the lecturer, who illustrated his remarks by means of experiments performed before an oxy hydrogen lantern, and thrown upon the screen through a double reflector. The transmission of heat through solids differing in amount with different bodies was illustrated by means of heating four bars covered with a thin layer of wax, the bars being of copper, brass, iron and glass. The bars transmitted heat in different proportions, thus melting the wax around them at different times. The copper bar transmitted heat the fastest. The brass and iron bars followed, and the glass was the last to melt the wax. This proved the relative conductivities of certain bodies and illustrated how bad and good conductors could be chosen. Glass, the lecturer said, was almost a non-conductor, while brass was, they all knew, used for pipes in engines. A table of relative conducting power was thrown on the screen. Silver was first, the capacity being taken at 100°, brass followed and bismuth came last, being only 2°. The lecturer here stated that when we became rich enough possibly silver might be used for the improvement of locomotion. An instance of the application of a bad conductor of heat was the asbestos glove used by the firemen of engines for taking up hot bodies without damaging their hands. The lecturer, by means of placing a sheet of asbestos on his hand, held a ball of red-hot asbestos without experiencing much inconvenience, and by making a hollow in his hand he averred that it was possible for him to hold anything hot on his hand for any length of time. This again introduced the next point of thelecture, viz., the small conductivity of most gases. He said that if he were to put water on his hand he could illustrate that liquids also were bad conductors. Air being a bad conductor of heat, double doors, walls and even double windows should be put in houses. After the same theory, clothing which contained the greatest amount of cells, notably silk, wool and felt, were the warmest because they could store up the largest amount of air. The lecturer here mentioned the Norwegian cooking box, which is made entirely of felt of various thicknesses. A fire is lit under it and the food is put in to cook and covered in with a felt lid. The fire is allowed to go out and the cooking box may be left for any amount of time up to ten or twelve hours, or until the meal is ready for consumption. This box is not only used for cooking purposes but is also an ice house, as when cool, the box will preserve ice for a long time. This, said the lecturer, was the first time he had heard of a cooking stove being capable of being used as an ice house. Proceeding, the heating of liquids and gases by transference of particles was illustrated, the heat being applied from below by a Bunsen burner. The heated particles becoming relatively lighter, ascended. This ascension of the heated particles was used in expelling the used-up air from mines. To illustrate this a large test tube was introduced and an oblong body was let down in it so as to cause a narrow passage of air round the side of the test tube in a U shape. At one side a small candle was burning, and at the other side a piece of smoldering brown paper was put. The smoke from the paper descended on one side and came up at the side the candle was on and out at the top.

Construction and Care of Wicks.

In the course of a paper recently read before the Edinburgh Association of Science and Art, on the "Burning of Mineral Oil in Lamps and Stoves," John Laing offered some useful information and advice in regard to the construction and care of wicks, of which the following is an extract: "With reference to wicks, said Mr. Laing, those made from long staple cotton draw the oil freely and regularly from a long distance and would empty any font without any diminution of capillary power, but tightly plaited wicks of short staple cotton have not so good capillary powers, and accordingly the flame was not supplied with such a regular supply of oil necessary for complete combustion and a good light. Such wicks are apt to char and also give a higher temperature to the burner. A wick rather on the loosely woven side is, on the whole, best for the majority of burning oils unless they were of light specific gravity, in which case one closely woven was considered the best. The quality of any oil could not be judged by its appearance when first lighted; it would be better to burn a font out till none was left, taking note of the character of the flame at intervals from beginning to end. A good distillation oil should not lose much in such a test, but chemically-treated oils would do so. It was not always the fault of the oil, however, when the light was poor and dropping; old wicks were frequently to blame. Before a new wick was used it should be dried before the fire, or put into an oven for a short time till no watery vapor comes from it, and while it was still warm it should be put into the oil. The longer a wick was used the worse lighting results it gave. When there was a double wick lamp or stove, one wick should never be left unlit, as the one lighted will char the unlighted one, and generate a dangerous amount of heat; and on no account should a wick tube be left minus a wick while the lamp was burning. When a lamp was not in use, the wicks should be turned down slightly below the top of the wick tubes. Lamps and stoves should never be charged only half full, because if vapors were given off in any quantity there was ample space for mixing with the air to a dangerous extent. On the other hand, brimful charges were very dangerous because of the expansion of the oil by the heat, which involved the risk of bursting the oil font. All wicks should be long enough to reach the bottom of the oil font; when they become shorter a new wick ought to be supplied. The question as to whether glass or metal fonts were the better was difficult to answer. Each had its advantages and disadvantages; but all glass fonts should be inside metal containers, as in that case there would be less danger if an explosion occurred.

The first gun of modern ordnance for the protection of New York is now in position at Sandy Hook. It is a 12-inch gun, weighing 51½ tons, and is mounted on a Snyder disappearing carriage. It is the first 12-inch gun built in this country. It was constructed at the Watervliet Arsenal, and has fully borne out all the expectations of its designers.

WORLD'S FAIR NOTES.

The Judges.

Much dissatisfaction was expressed last week because the names of the appointees for judges were not announced in all the departments. Those appointed for the department of electricity are as follows: H. S. Carhart, Ann Arbor; H. J. Ryan, Pennsylvania; B. F. Thomas, Columbus, Ohio; George F. Barker, Philadelphia; T. C. Mendenhall, Washington, D. C.; Robert E. Owen, Lincoln, Neb.; Michael O'Dea, Notre Dame, Ind.; W. M. Stein, Chicago; Samuel Reber, United States Army; H. A. Rowland, Baltimore, Md.; E. P. Warner, Chicago.

The judges had been appointed because they were expected to get together on Saturday in the different buildings and organize for work.

Scotchmen Come Here to Learn.

One of the most noteworthy arrivals at Jackson Park last week was "The Artisan Expedition to America," projected by the *Courier* and the *Weekly News* of Dundee, Scotland. The party consists of ten specialists in the departments of metallurgy, electricity, textile, shipbuilding, paper making, mining, building, transportation, agriculture, and wood working, under the conduct of James Murray, formerly chief reporter of the two newspapers. Its object is the acquisition of reliable information concerning the conditions of the American wage earners, how they live, what kind of houses they have, what hours they work, what leisure they enjoy, and what kind of food they get.

Electricity Lectures Practically Illustrated.

Chief Barrett has arranged for a series of lectures in Electricity Building that are expected to prove a popular feature of World's Fair education. The lectures will be given daily by experts in charge of exhibits, each man selecting the subject in which he is best equipped for discussion. After each lecture the audience will accompany the speaker to the exhibit that has been under discussion and a practical illustration of the talk will be made.

Most of the exhibitors in Electricity Hall have agreed to assist Chief Barrett in carrying out his plan, and he is confident that the course will prove of great interest to students of electricity.

Attendance and Profits.

During the month of June the World's Fair cleared, above all expenses, $1,017,898.94. The receipts for the second month, as returned by Auditor Ackerman, were $1,660,820.21 and the expenditures $642,921.27.

Contrasted with the first month of the exposition this result is all that the managers could desire and more. The receipts for May were $719,402.71 and the expenditures $609,883.87, leaving a profit for that month of only $109,518.84. The profits for the second month were consequently ten times as great as for the first four weeks.

It is unreasonable to expect anything like that increase during any of the following months, but the gain is steady, and July will show a much wider margin of profit than June, which was fully up to the expectations of the managers. Aside from the large increase at the turnstiles, the returns from concessionaires will be much greater. The managers have settled most of the disputes with concessionaires, who held back their funds waiting for compromises on account of the delay in getting their electric lights in place. The revenue from concessions is expected to reach $20,000 or $25,000 a day from now until the close of the fair. Mr. Ackerman's report, which closed June 30, shows that $580,006.36 had then been realized from concessions. Since that date large payments have been made by shop keepers and others doing business on the grounds.

The report shows that $1,286,675.26 was due contractors on July 1, but Mr. Ackerman says this was largely reduced after the report was made up. The largest amount due on any one contract was $260,469.58 for the electric light plant. The heavy receipts by the fair are particularly gratifying on this account, because so many contractors were creditors after the gates were thrown open to the public. Quite a number of Chicago firms were put to great inconvenience by reason of the non-payment of their claims on the completion of work. The disbursements are a little late, but they will make the times more endurable.

The Jurors.

Full information regarding World's Fair Judges of awards is not yet accessible. The following jurors for Manufactures Department, nominated in executive session sometime ago, were confirmed for the groups named on the 21st inst.:

Glass and Glassware.—R. M. Atwater, Syracuse, N. Y.; John Corcoran, Wheeling, W. Va.; Charles Colne, Brooklyn, N. Y.

Chemical Products—Professor Appleton, John Brown University, Providence, R. I.; Prof. C. F. Chandler, Columbia College, New York; Major King, U. S. A., Willetts Point, N. Y.; George E. Lorenz, Toledo; William McMurtie, New York City; Prof. Albert Prescott, Ann Arbor, Mich.; Prof. W. B. Rising, Berkeley, Cal.; Prof. Ira Remsen, Johns Hopkins University, Baltimore; Prof. S. P. Sharpless, Boston; William Simpson, Raleigh, N. C.; Prof. Edgar F. Smith, University of Pennsylvania, Philadelphia; Waldron Sharpleigh, Gloucester, N. J.; Marcus Salmon Benjamin, New York; J. D. Humphrey, Huntsville Ala.

Paints and Dyes.—J. B. Brewster, New York City; Dr. M. H. Drummond, New York City.

Ceramics and Mosaics.—Dr. W. S. Bigelow, Boston; Walter S. Lenox, Trenton, N. J.; Professor Morse, Boston; Henry Loomis Nelson, Washington, D. C.; Salomon P. Stratton, Boston.

Plumbing Materials—H. E. Bullock, Illinois; W. E. Clow, Chicago; Morton Y. Cady, Moline, Ill.; Hugh H. Hannah, Indianapolis.

Cooking and Heating Apparatus.—Romyn Hitchcock, Washington, D. C.

Monuments and Undertakers' Supplies.—Dr. J. Henry Jackson, Barre, Vt.; L. G. Laurean, New York City; Charles H. Morgan, Worcester, Mass.

Scales.—Samuel H. Howard, Caledonia Springs, Vt.

Wrought Iron and Thin Metal Goods.—J. L. Ketcham, Indianapolis; G. W. West, Birmingham, Ala.

Gold and Silver Ware.—David Pell Secor, Chicago.

Stained Glass in Decoration.—John C. Carpenter, Kansas; John La Farge, Judge A. B. Quinton, Topeka, Kan.

Carvings in Various Materials.—A. H. Dainty, Chicago.

Materials of War, Hunting and Sporting Goods.—W. C. Dodge, Washington, D. C.

Safes, Hardware and Cutlery.—John Griffith, Philadelphia; E. R. Strauss, Chicago.

Typewriters, Paper and Stationery.—Charles L. Hamilton, Philadelphia; C. A. Lownsberry, North Dakota; E. Morgan, Springfield, Mass.; William O'Shea, Lincoln, Neb.

Judges Named but Not Assigned to a Particular Group.—Prof. E. C. Carpenter, Ithaca, N. Y.; Hounton Chapman, Uniontown, Ky.; Ernst Fenelosa, Boston; F. D. Higbee, Chicago; H. H. Jackman, Kansas; G. W. Johnston, Hastings, Neb.; H. I. Kimball, Atlanta, Ga.; Russell Sturgis, New York City; Charles A. Schaeffer, Iowa City, Iowa; John W. A. Strickland, New York City; L. W. Williams, Oak Cliff, Texas; Robert D. Williams, Albany, N. Y.

Although some of the judges are already at work inspecting and comparing exhibits, the full list will not be given to the public until some time this week.

The Judges Organize.

The judges met on the 15th inst. to arrange for the work of examining exhibits and making awards. Those appointed for Mines and Mining held their meeting in the reading room of that building. About forty members were present. Prof. J. C. White, Professor of Geology and Mineralogy in the University of West Virginia, was elected president. The matter of selecting two vice-presidents was left to the foreign jurors, to report the names of two of their number at 2 o'clock Monday afternoon. Joseph D. Weeks of Pittsburgh, Pa., was chosen secretary. He will be given a paid clerk, upon whom the burden of the clerical work connected with the office will fall.

The departmental committee for machinery met in its room at 1 o'clock, in the east gallery of Machinery Hall. The following judges were present:

George H. Barrus, Boston; Prof. Lewis S. Rober, Pennsylvania State College; O. E. Smith, Norfolk, Va.; William Sooy Smith Chicago; R. H. Thurston, Ithaca, N. Y.; W. C. Lamont, Bucyrus, Ohio; Marcellus Gould, Manchester, N. H.; Frank P. Holt, Laconia, N. H.; William C. Margodaut, Hamilton, Ohio; Thomas R. Pickering, Portland, Conn.; Francis J. Reiss, Evansville, Ind.; A. J. Monovale, Washington, D. C.; Prof. Jones, Adams, Mass.; John A. Roche, Chicago; James Denton, Stevens Institute, Hoboken, N. J.; L. C. Billings, William Y. Young, Medford, N. H.

The committee elected John A. Roche chairman and P. A. Bloom vice-chairman, and then adjourned to 11 o'clock Monday.

The judges of the section covered by exhibits in the Manufactures and Liberal Arts Building met in a committee room in that building. It was decided to make a division of the work here, and two chairmen were designated—Dr. Buenz, in charge of the Artistic Manufactures and H. I. Kimball in charge of Commercial and Economic Manufactures. Mr. Kimball, is from Atlanta, Ga., and was the director general of the Atlanta exposition. A. B. Kendrick of Boston was elected secretary pro tem. An adjournment was then taken to Monday to receive specific instructions with regard to exhibits to be examined.

THE RETAIL STORE.

Local Checks.

We are in receipt of a letter from the correspondent in Virginia whose communication in regard to the payment of bills by checks on local banks called out the article in our last issue from a "Long-Suffering Jobber." In this letter our Virginia correspondent takes exception to the position of the jobber in which reference is made to the method of paying with local checks as "a system of petty robbery." Our correspondent then continues:

I will call his attention to the fact that he has overlooked the strongest point in my article, which was that in trade as in war it is useless to complain of your adversary's manner of conducting the campaign, and that the only thing to be done is to apply such remedies or acts of retaliation as are at hand, and this the "Long Suffering Jobber" can do by returning the checks to those who send them to him. If he is thoroughly consistent and really wishes to keep out of their hands, let him instruct his salesmen not to solicit their business, and further let him erase their names from his list of those to whom to send circulars, and we opine that he will not be longer a victim of such injustice.

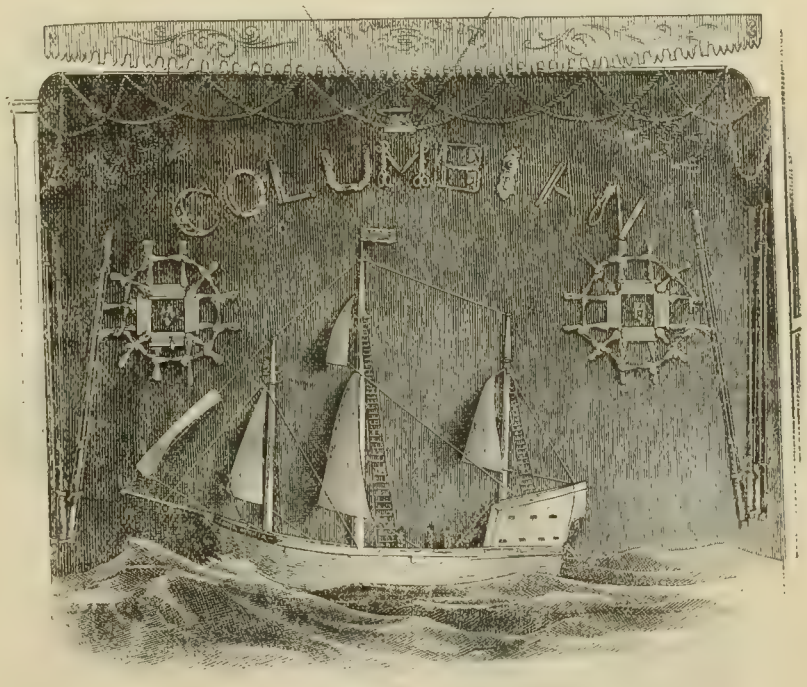
Touching upon the same subject we have the following communication from a prominent New England manufacturer, in which it will be seen that while our correspondent disapproves of the payment of accounts by local checks, he is pleased to receive them and to pocket the loss entailed in their collection:

I have read with interest the communications from "Banker" and "Retailer" and the replies thereto. Unquestionably "Banker" is right, and local checks do not pay in full, but are an imposition on the creditor or his bank of whatever the cost of collection may be. To be strictly just, the debtor in sending them to a distance should make them payable "with exchange," which makes them worth par anywhere (if of any size). Amounts less than $1 should be sent in postage stamps.

Ten years or more ago we used to complain of local checks. We do so no more, and are only too well pleased if customers in the United States or Canada send us local check promptly when bill is due. Not that it is right, for customers should send funds worth par, but the custom is growing with many buyers. Some do not think and others do not care. Others are ignorant—for instance, the man who sends New York draft for $49.75 to pay a bill of $50, charging the exchange to his creditor.

Window Arrangement.

From the State of Washington we have an example of up-to-date window dressing. Cochran Bros., Montesano, Wash., favor us with a photograph of a window picture, which is reproduced in the accompanying illustration. The Columbian year is well represented here by Hardware articles, as everything used in the make-up of the picture, except the background, is directly connected with the Hardware and Metal trades. The hull of the ship is of sheet lead, the sails of building paper, the masts of tin, the rigging of copper wire, and the water of green wire cloth. A Cross-Cut Saw forms the top of the picture, with Coil Chain looped beneath, in the center of which is suspended a small Anvil. The word "Columbian" contains Chain, Dog Collars, Coil Spring, Rules, Scissors, Safety Chain, Wire Nails, Drawer Pulls, Escutcheon and Rose, Carpenter Pencils, Hog Ringer, and Bit. The wheels on either side are made up of Fish Lines on blocks and in hanks, with Reels in the center. It is hardly necessary to add that the window attracted a great deal of attention, and that the enterprise and ingenuity shown in getting up so elaborate a design were favorably commented upon.



Columbian Window Dressing.

Husking Gloves No. 45.

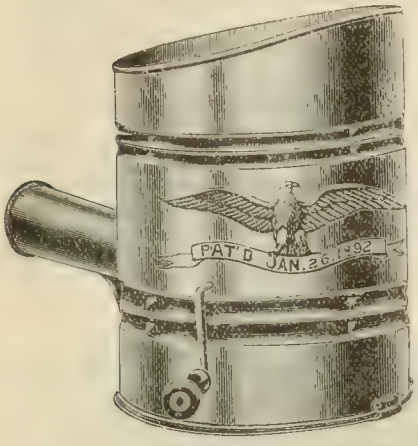
Hall & Ross Husking Glove Company, 253–259 Elston avenue, Chicago, Ill., are introducing the gloves herewith illustrated. The manufacturers state that the gloves are made of oil-tanned hog skin, as one of the best wearing leathers for hard work, and that it overcomes the great trouble found in using cheaper leather, as being oil tanned it will not harden by wetting.

Husking Gloves No. 45.

The company advise us that they have enlarged their manufacturing department and are fully able to take care of all their trade, including the United States and Canada.

The Eagle Sifter.

Sills & Grossman Company, 86 Lake street, Chicago, have brought out an improved Flour Sifter, which is herewith illustrated. The Eagle Sifter, as it has been called, operates on the same principle as other rotary Sifters, but in addition it is provided with a patent bottom, which can be closed, as in Fig.



The Eagle Sifter.—Fig. 1.—Sifter with Bottom Closed.

1, when not in use, thus preventing the flour from escaping when placed upon the table or pantry shelf or while being carried about the kitchen. It thus prevents the loss of flour and, being more cleanly than a bottomless sifter, commends itself to thrifty housewives. The bottom is hinged to the body of the sifter and is so accurately fitted that it makes a very tight joint. It is held in place by a brass spring, which requires but a slight pressure to

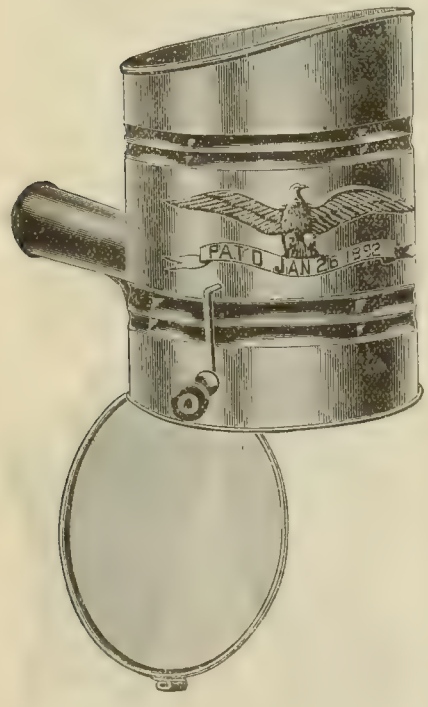


Fig. 2.—Sifter with Bottom Open.

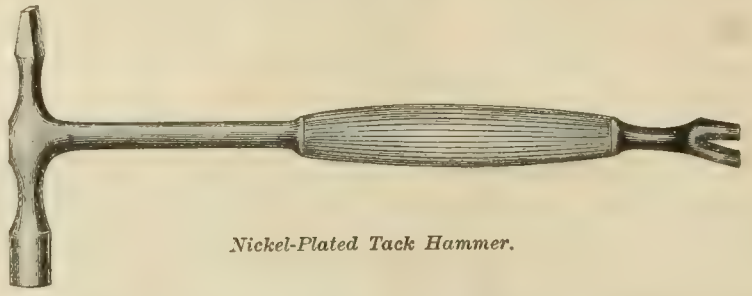
let the bottom down ready for use, as in Fig. 2. The body of the sifter is made of the best quality of tin plate, the crank is strongly made so as to endure much wear, and the top is finished with a sharp edge so as to scoop flour easily.

Nickel-Plated Tack Hammer.

Troy Nickel Works, Troy, N. Y., are offering a tack hammer as herewith

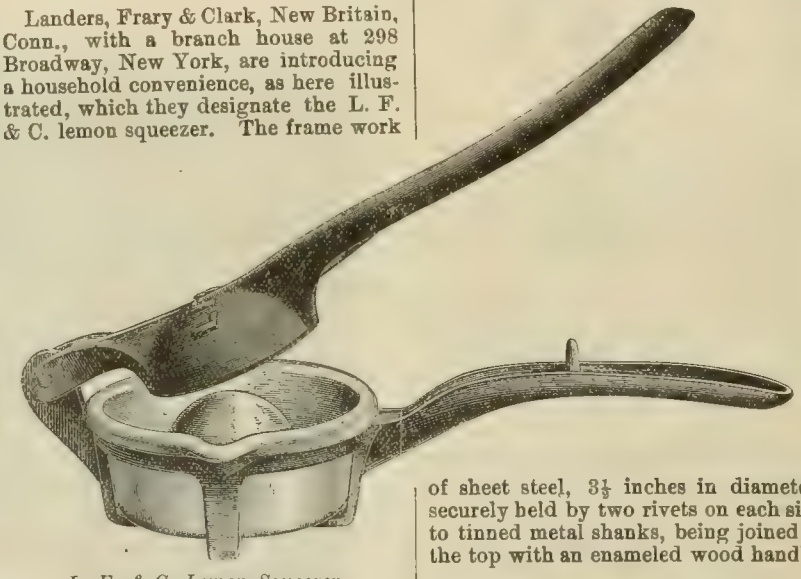


Nickel-Plated Tack Hammer.

shown. The hammer is made of steel, full nickel plated, with the handle part of rubber. The manufacturers refer to the article as being especially adapted to ladies' use.

L. F. & C. Lemon Squeezer.

Landers, Frary & Clark, New Britain, Conn., with a branch house at 298 Broadway, New York, are introducing a household convenience, as here illustrated, which they designate the L. F. & C. lemon squeezer. The frame work

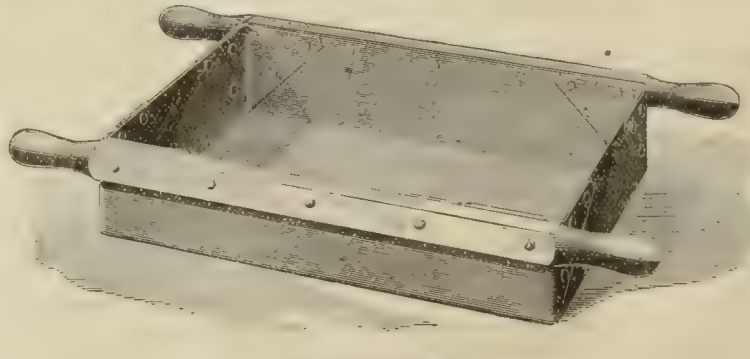


L. F. & C. Lemon Squeezer.

is of iron japanned, the under portion being so constructed as to furnish a firm support for the cup of block tin into which the juice is forced. This cup will receive the juice of two or three lemons and has a lip on one side, which insures a good pour. The squeezer is 10 inches long, the cup being nearly 4 inches across and 1½ inches deep.

New Hand Barrow.

W. J. Clark & Co., Salem, Ohio, are manufacturing a new kind of hand



New Hand Barrow.

barrow made of sheet steel, an illustration of which is given herewith. The manufacturers claim that the barrow is lighter, more durable and cheaper than barrows made of wood, and state that for use in shops and factories, where hot metal articles have to be handled, it is especially desirable. They also remark that they are useful and economical in many places where wheelbarrows cannot be used.

Ring Chopping Knife.

E. S. Anderson, Gloversville, N. Y., is offering a ring chopping knife, as here illustrated. It consists of a ring of sheet steel, 3½ inches in diameter, securely held by two rivets on each side to tinned metal shanks, being joined at the top with an enameled wood handle,

Chopping Knife.

held in position by means of a long rivet. The extreme hight is 5 inches. This gives 10¾ inches of chopping edge, which will not clog. It can be quickly cleaned and easily sharpened. This article is marketed through James A. Bogardus, 167 Chambers street, N. Y., as sales agent.

The Electric Vise.

The Capital Machine Tool Company, Weedsport, N. Y., are offering the trade a line of vises, represented by the machinist's swivel-bottom iron-workers' vise, shown in Fig. 1, the construction of which is given in detail in Fig. 2. The vise is of the rapid transit pattern, and requires, it is stated, only one movement in and out, one turn of the hand, to secure the work. The manufacturers remark that the vise is strengthened in parts subjected to wear and strain to prevent the breaking and wearing out of the mechanism in the engaging parts. An anvil is made on the back and top part of the vise, and the vise body reaches across full width to allow for a large range of work. The adjustable jaw is shown in Fig. 3, which is referred to as being well made and tempered. These are furnished either checked or smooth. The pipe chuck attachment, Fig. 4, is made of solid steel, one set of the jaws being fitted rough and the other set made smooth for finished work. The advantages claimed for this arrangement of chuck in connection with this vise are that it is quick and easily swiveled to any angle for long or short work; that it holds the work firm and steady without crushing: that the work is instantly placed in the vise jaws or taken out, avoiding the use of set screws or taper pins, and that it is a durable device for holding long or short pipes, rods or bolts. The chucks are made in ten sizes to hold pipes, &c., from 0 to 6 inches. At present only one size of vise is ready, this being No. 15, weighing 45 pounds, but in a short time the manufacturers expect to have nine different sizes on the market.

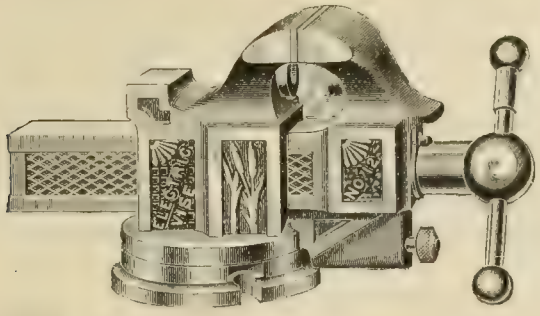


Fig. 1.—The Electric Vise.

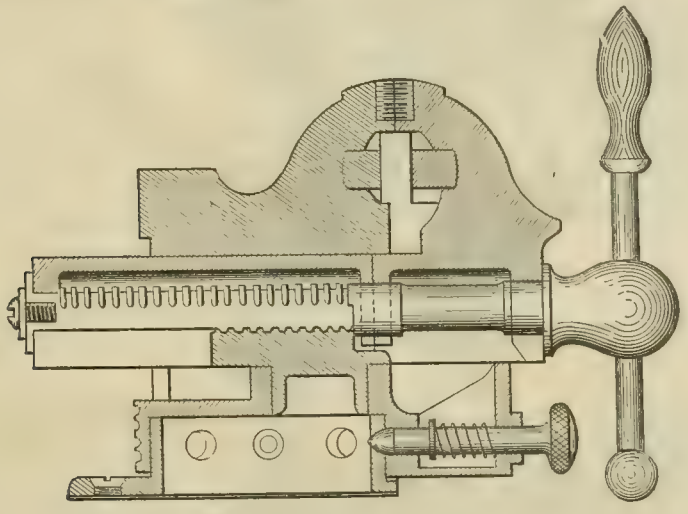

Fig. 2.—Electric Vise in Detail.

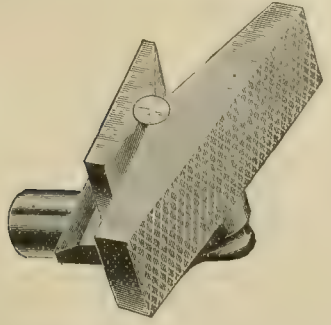

Fig. 3.—Adjustable Steel Jaw Attachments.

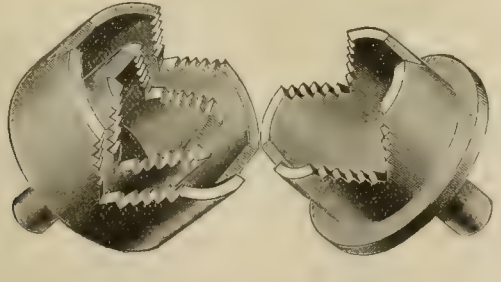

Fig. 4.—Little Giant Pipe Chuck.

Odorless Stew and Fry Pan.

The Wilmot & Hobbs Mfg. Company, 20 Murray street, New York, are introducing an automatic cover-raising and emptying odorless stew and fry pan, as illustrated herewith. The utensil is stamped seamless from smooth surface, cold rolled Swedoh steel, with the odor flue riveted on the outside. Fig. 1 shows the pan in use with the cover closed, and with the bail and cool handle in a vertical position out of the heat and away from the other utensils on the stove. The point is made that the handle is always cool and not in the way, as with a saucepan or spider handle. The cut also indicates the way in which the fumes of cooking onions are carried up the stove pipe. In Fig. 2 the lid of the pan is automatically raised by pressing down on the handle, while it is explained that the reverse motion instantly places the cover again in position over the pan, and that the lid can be automatically raised by depressing the handle in either direction. The cover can be raised and the handle automatically locked in position to pour the contents from the pan, as illustrated in Fig. 3. The cover and handle are removed for shipping by taking out the hinge pin. The manufacturers claim that the utensil is light and durable, heating evenly and quickly and is instantly adjusted by the cool handle; also, that it is sure to prevent all odors and smoke from filling the room. The fact is emphasized that burning the fingers is avoided, as the cover works automatically and is always in place.

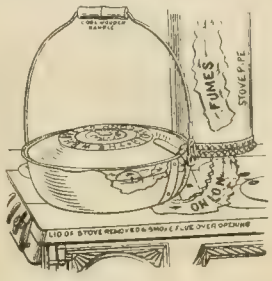

Fig. 1.—Odorless Stew and Fry Pan.

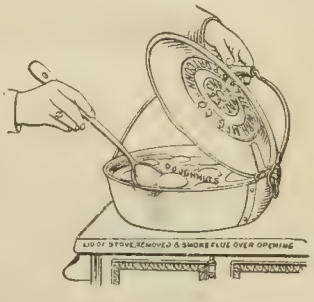

Fig. 2.—Automatic Cover Raiser.

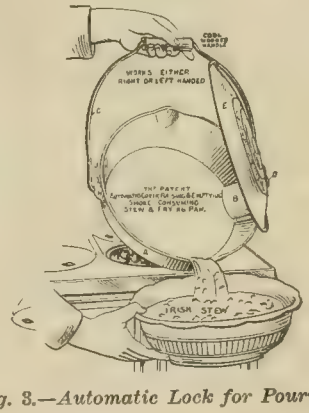

Fig. 3.—Automatic Lock for Pouring.

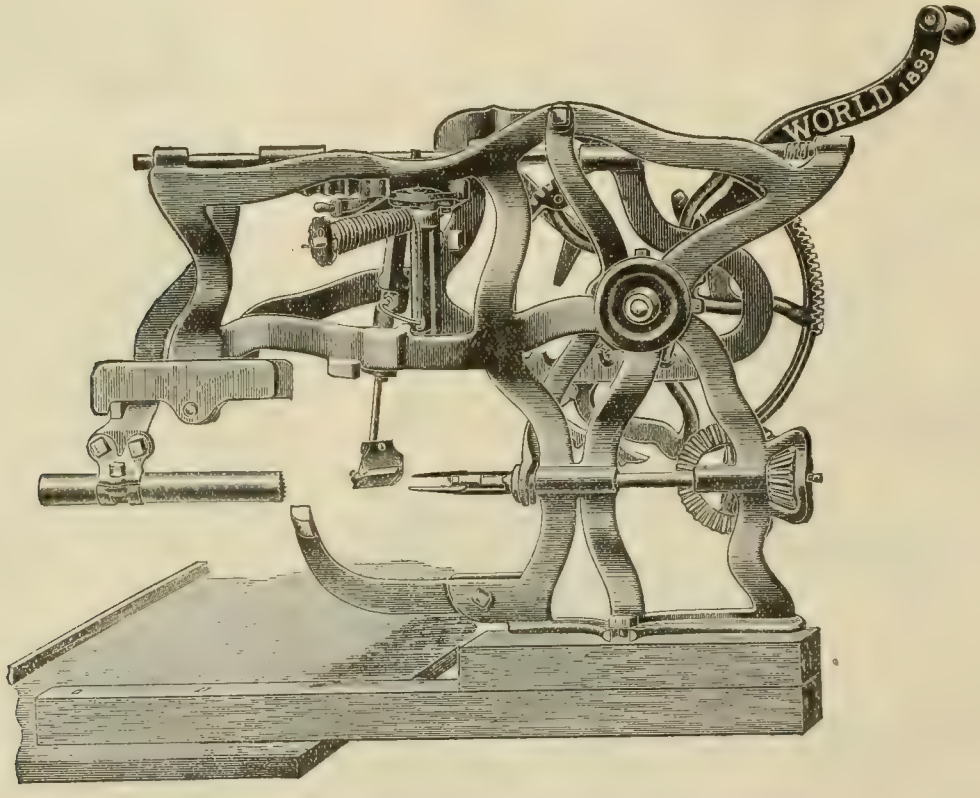
The World Apple Parer.

C. M. Heffron, Rochester, N. Y., is the manufacturer of the new apple parer represented in the accompanying illustration. Attention is called to the simplicity of the design and the few parts. An effort has been made to adapt the operation of the machine to the most natural movement of the hands. The parer is referred to as a one-turn machine, requiring but one turn of the crank to pare an apple. It is claimed that expert operators can run this machine without stopping, slacking down the speed to about one-half while putting the apple on the fork.



The World Apple Parer.

The Bear's Tail and Wire Nails.

BY THEODORE.

"Yes," said Joe Blackburn (the truthful Joe), "that was about the funniest experience I ever had on the road."

"'Nuther ghost story?" questioned one of the crowd in rather a disgusted way.

"No, siree; this occurred; this did!"

"Well! that is remarkable," said the questioner with pretended astonishment; "actually going to tell the truth. Well! the profession is going to the dogs sure nuff."

"I tell you this is all straight," said Joe.

"All right; go on."

"Well, I was traveling for a Hardware firm, trying to introduce a new line of goods into New England, and was meeting, of course, with immense success ——."

"Oh, of course!" came the sarcastic chorus from the crowd.

"With immense success, as I was saying," he continued not minding their chaff. "Well, it so happened, that in working through Maine I had to call at a small town, which was not much out of my way, in order to see an old fellow from whom we bought our axe handles. There was no trade in the place—regular woods, you know—and I did not expect to stay more than a few hours at the most, especially as it was in the middle of winter, and with no decent hotel in the place. I found the old fellow's place all right—queer old shop—and after we had settled the business on hand I started to go, intending to catch the one afternoon train; but he stopped me and invited me to stay overnight and join with him in a bear hunt on the morrow. Of course I stopped, for if there is one thing that I like more than another (and there is), it is skating across the snow, hot on the trail for bears. I ——"

One of the party interrupted: "Sure, it was not a cow or chipmunck, or something of that kind you were after?"

"It was bear, straight bear; suppose you will say next that I never saw one.

"Well, the next morning we started out with a rifle and an old breech-loader. We were not an hour's distance from the town when we struck a fresh trail, which must have been made that morning, as it had snowed lightly during the night. We kept on for about an hour longer, following the trail, which led us to a steep cliff, and we had a slippery time climbing up. The old man was carrying the rifle and he also had the shot for the breech-loader which I carried. We had just reached the top when by some mishap he slipped and down went the rifle and shot to the bottom of the cliff into a deep brook. Almost at the same moment we spied bruin making for us. There was no time to lose, so I drew the old breech-loader to my shoulder and fired. The shot missed, and on came the bear.

"'There is no more shot. We'd better run,' shouted the old man.

"Suddenly I bethought myself I had plenty of powder and in my pocket was a package of our justly celebrated Wire Nails. I hastily loaded the gun with them, and as the bear was passing a large tree I took aim and fired. The bear came to a sudden stop; but he did not seem hurt, and I prepared to load up again, when the old man burst out laughing.

"'Confound it,' he said. 'Blamed if his tail ain't nailed to the tree.'

"I looked, and was astonished to see the bear tugging away endeavoring to free himself. The Nails had struck him as he was passing the tree and his tail was firmly nailed to the bark. Well, we went up and dispatched him with a knife; but it took us nearly an hour to extract the Nails, and I have them yet, which proves the truth of my——"

"Joe," interrupted one of the crowd, "Joe, did you ever read the story about George Washington and the cherry tree?"

"Yes."

"Well, read it again."

STOVE TRADE NOTES.

The Future of the Hot-Air Furnace.

By A. W. Glessner,

President of the Excelsior Steel Furnace Company.

DECREASING COST OF FURNACE WORK.

In almost every attack on the hot-air furnace I notice that the fact that the prices realized in this branch of heating have been and are on the decline is cited as a reason for the decadence of the business. There has been a decline in prices, and this is to my mind the most hopeful feature of the business from the standpoint of the dealer, though discouraging to the manufacturer, who finds it very difficult to make a profit on a lowering market. To be sure, the cost of producing furnaces is decreasing yearly, partly by the steady fall in the cost of pig iron and steel, though a very small decline is reflected on the cost of sheets, and partly by better management in the foundry and finishing departments, which have reduced the cost of labor somewhat—but the cost has not gone down as rapidly as the selling price, which is due to the ever increasing competition in this line of manufacture. No article that enters into the equipment of a house is sold so much below its actual value as the hot-air furnace, and the outlook is not for very much higher prices, and the money must be made from the large increase in sales which these close prices should effect. In many sections of the country fair prices are obtained by the furnace manufacturer, but in the large centers the prices now ruling are abnormally low.

POSITION OF THE DEALER.

This places the dealer in a position to supply a furnace to the consumer at a price that should surely lead to ready sales during the normal times. At present the financial stringency may affect the sales somewhat, but the demand will be renewed later. In a city in the northwest of about 10,000 inhabitants one enterprising dealer recently told me that in 17 years he had placed nearly 200 furnaces, and had seen the price of the completed job drop from over $400 on an average to considerably less than $200 at the present time. This dealer took one of the prizes in *The Metal Worker* competition some years ago, and has made a careful study of his business.

DECREASED COST.

The decreased cost of furnace work is due not alone to the lower prices ruling on furnaces, but also to the reduction in the cost of registers, fittings and labor in installing jobs. The workman has grown more expert, and while paid more per hour now than formerly, he manages to perform more work in a given time. I have records of the cost of material and labor on numbers of jobs done several years ago by our company, and on looking them over I am surprised to note the lessening cost of the material, and this notwithstanding the increased cost of the tin plate entering into the fittings used. This is due to machinery, however, and at another time I will refer to the change in this department of furnace work.

In registers the decline has been pronounced, the goods being sold on closer and closer margins, and only the increased production has saved the makers from absolute loss.

Furnace heating is not the only branch that has suffered from the decline in prices. The steam and hot-water trades have much to complain of in the same vein, and it has required the greatest care to earn anything on the capital invested.

Radiation has gone down materially, and prices in all branches of heating have reached a low level.

(To be continued.)

The Detroit Stove Works

of Detroit, Chicago and Buffalo, have issued an exceedingly attractive catalogue showing their lines of cook stoves, ranges and heaters. The assortment is a varied one, embracing constructions adapted to meet all reasonable requirements of the trade, and the goods are offered in a style of ornamentation which cannot fail to please the eye of the dealer who is inclined to be artistic in his tastes. After a statement of terms, remarks relative to prices and advertising material and the presentation of a telegraphic code for use in ordering goods by wire, attention is invited to the Jewel wrought steel range, which is made in seven styles and four sizes. It is adapted for hard coal, soft coal, coke or wood, and embodies a number of special features, reference being made to the wrought steel oven plates, the oval fire pot, the sheet flue construction and the water coil front and back. Next in order we find the Buffet Herald steel range, designed to burn the same kinds of fuel mentioned in connection with the previous construction, and made in three sizes and six styles, several of which are illustrated. The general line of stoves made by the company, whose catalogue is under review, is known under the name Jewel, and something like 50 pages are devoted to ranges. These are offered under such names as the Merit Jewel, Empire Jewel, Prize Jewel, Pacific Jewel and Atlantic Jewel. Following these we find the cook stoves occupying something over 30 pages, and these in turn are followed by the heaters, with the Imperial Jewel base burner occupying the place of honor. This is a richly treated parlor stove intended for burning hard coal. Special reference is made to the automatic feeder cover, the fire pot, grate, ash pan, swell front, mica illumination and tea kettle attachment. A sectional view is presented showing the flue construction. The Crown Jewel, for hard coal, a new high-grade base burner made in three sizes; the Peerless Jewel, a medium-priced construction; the Radiant Jewel, a richly treated surface burner; the Fire fly Herald, an attractive Franklin; the Sunlight Jewel, another member of this class; the Oak Jewel; the Royal Jewel, a wood burning cottage parlor stove of handsome ornamentation; the Herald Box, together with a line of laundry stoves and farmers' boilers are presented. The closing pages of the catalogue are devoted to a list of repairs for Jewel stoves, an index to the telegraphic code, cuts of trademark intended for use by the company's customers for advertising purposes and a general index.

The New Plant of the Scranton Stove Works.

The first heat at the new plant of the Scranton Stove Works at Dunmore, Pa., was poured at 3 o'clock on the afternoon of Tuesday, July 18. The plant is fully equipped in every department for the rapid production of high grade goods, and in the erection of the buildings the company have not neglected the comfort of their employees. A representative of one of the Scranton papers recently visited the works and from the account which he gives of the plant we take the following particulars:

The floor has a concrete base 5 inches thick. Into this are imbedded oak sleepers and on these are 2-inch hemlock planks, on top of which is a flooring of 1¼ inch yellow pine. This makes a floor so solid that teams drive over it without jarring the building. Another advantage that it possesses is, that rats or mice cannot get beneath it, and the danger from fire is reduced to a minimum. The roofing is tongue and grooved hemlock and spruce, 2½ inches thick, covered with fire proof granite $\frac{3}{10}$ inch in thickness.

Every detail in the arrangement is complete, and workmen or visitors go from one department to another through aisles or gangways 10 feet wide, which enable teams, if necessary, to go in and out. Elevators are erected in convenient places so that the storage department can be reached without loss of time. An inclined trestle outside the works facilitates the handling of supplies, coal being introduced to the boiler room direct from the cars by means of a chute, and the sand used for molding goes into the foundry by a similar process. In the wareroom will be two elevators, one hand and one power. The works are located at Jefferson avenue and New York street, in the borough of Dunmore, and 200 feet outside the city line. They are reached by either of the suburban lines of the Scranton Traction Company which pass New York street two blocks from the plant.

THE FOUNDRY.

The foundry or casting room is 165 x 196 feet. It is in a flood of light. The cupola is in the center of the room to the side, and is equi-distant from all the farthest parts of the floor. The time required to carry a ladle of metal to any floor in the foundry being 33 seconds. This department is so constructed that 130 men can find employment—twice as many as could be employed in the old shop.

The cupola used for melting the iron is a straight one, with two charging

doors. The charging floor is light, airy and spacious, sufficiently so that a three-days' stock of coal and iron can be kept there without inconveniencing the workmen. The cupola has a capacity of about 12 tons per hour. It is double lined, and, in case it is desired to increase its capacity, one set of bricks can be taken out.

The stock yard is outside the works close to the cupola. Small cars for carrying the stock will run at the base of the trestle above referred to. When loaded it will be run on the elevator and taken to the cupola, where it is weighed. The company make a practice of weighing everything that goes in and that comes out of the cupola, being thus enabled to determine to exactness the loss in any particular grade of iron. The floor beams and plates surmounting the cupola are of steel. It is incased by four brick walls and the roof covering it is of corrugated iron. There is noting about it that will burn.

CLEANING ROOM.

Passing from the foundry the visitor finds himself in the cleaning room, the two being separated by a fire wall of brick. In the cleaning room are the rattle boxes, cleaning benches and the edge polishing machines. When the castings are cleaned they are put in a counting room and locked up. The next day they are counted and each man is credited with the product of his labor. There are two counting rooms, one for each alternate day.

FINISHING THE STOVES

After the castings are counted they are taken into the nickel-polishing room. Here they are put through a process incident to nickel plating. This room is 70 feet square, and carries nickel tanks, dynamo, hot and cold water tanks, potash and vitriol tanks. Adjoining this department is the mounting shop, where everything in that line needed in the stoves is manufactured. Adjoining this room is the pattern-fitting room, where all iron patterns for castings are filed and fitted.

The center of the mounting room, which is 145 feet by 200 feet in area, is given over to storing castings, raw material and brick used in manufacturing, and the New York street side of the room will be given over to mounting or putting the stoves together. Thus it will be seen that the process of making a stove is continuous. Light is furnished in the center of the mounting department by means of a monitor 35 feet by 80 feet in size.

Two 80 horse-power boilers made by I. A. Finch generate the steam needed in running the plant, and a 120 horse-power engine furnishes the motive power. The engine was built by the Dickson Mfg. Company, and the gentlemen connected with the stove works pride themselves on purchasing all supplies, when possible, in Scranton.

Besides the apartments described there is a three-story warehouse 40 x 100, in which will be shipping and advertising rooms and offices. This building has a basement that can be used for storage or manufacturing. A shipping platform outside the warehouse will be covered, and will be built up to a switch to be put in by the Erie & Wyoming Valley Railroad Company. In addition, there is a carpenter shop 30 x 56, two stories, and pattern shop 30 x 60, two stories, and a fire-proof building for pattern storage.

CONVENIENCES.

The company have expended in the neighborhood of $100,000, but much remains to be done. There is a tract of land at the rear of the works, 160 x 675 feet in dimensions, which can be used for dumping purposes. The entire area must be fenced, and much grading must yet be done. It is the intention of the company to introduce the Smead system of closets for the use of the men, and the boiler stack was built with this end in view. Bathrooms for the men will also be erected as soon as possible. The contract for heating every part of the building with steam is let to Hendricks & Co. of Carbondale, and the average heat will be 60°.

The plant contains improved methods, and it would be hard to find in any other place buildings covering several acres where it is possible to see all the men employed at the same time. The company own 30 lots in the vicinity of the works, on which it proposes to erect houses, which will be sold to employees at a reasonable price and on easy payments. Architect I. L. Williams prepared the plans for the buildings.

Veteran Stove Manufacturer.

To celebrate the fiftieth anniversary of his entry into the stove trade, Isaac A. Sheppard, the respected head of the well-known stove manufacturing firm of Isaac A. Sheppard & Co., Excelsior Stove Works of Philadelphia and Baltimore, 200 of his employees gathered at a banquet at Warner Hall, Philadelphia, on Saturday, July 22. Mr. Sheppard presided, and the five tables were respectively headed by the foremen of the different departments in the works. After dinner a gratifying surprise awaited Mr. Sheppard in the shape of a handsome silver cup, which was presented to him by Frank Lawrence, one of his oldest workmen, on the part of his fellow employees, as a token of their respect and esteem. The cup bears on one side the firm name, with the names of Franklin L. and Howard R. Sheppard, sons of Isaac Sheppard, and partners with him. In the center is a stamp bearing the "Excelsior" design, and on either side of the coin are views of the firm's two stove plants at Philadelphia and Baltimore.

Isaac Sheppard, who is one of the veterans of the stove trade, was born in Cumberland County, N. J., and is, says the Philadelphia *Ledger*, a descendant of two of the oldest families in the State—the Sheppards and Westcotts. He went to Philadelphia with his parents in 1840, both of whom died shortly after, and young Sheppard was forced to make his own livelihood. For a time he drummed up trade for the 'buses, which in those days were almost the only means of passenger conveyance, his duties consisting chiefly in calling out their destination and various stopping places to the crowds at the ferries.

In 1843 he apprenticed himself to the molding trade with the firm of Warnock & Co., where he remained until he had thoroughly mastered the business. In 1859 the firm of Isaac A. Sheppard & Co. was formed, and began business at Marshall street and Girard avenue, Philadelphia, proving so successful that a branch works was started in Baltimore seven years later. In 1871 the business at Girard avenue increased so rapidly that the present plant on Fourth street was secured. It covers four acres of ground, taking in the entire block from Montgomery avenue to Berks street, from Third to Fourth, the buildings having been previously used as the Fifth and Sixth streets car depot.

While giving close attention to business, Mr. Sheppard still found time to devote to political and educational matters. In 1858 he served the People's party in the Pennsylvania Legislature, and was twice re-elected, and while there was unanimously elected Speaker *pro tem.* In 1879 he was appointed to the Board of Education, and ten years later was elected president of that body. He was also one of the first to establish building associations in Philadelphia, and is still connected with several savings institutions. He is at present President of the National Security Bank, Franklin street and Girard avenue; trustee of the Northern Savings Fund, Sixth and Spring Garden, and of the Northern Liberties Gas Works. He is a Past Master in the Masons, Past Grand Master of the Odd Fellows and has been elected Treasurer of the Sovereign Grand Lodge. Among his charities Mr. Sheppard numbers a Memorial Home for Consumptives at Chestnut Hill, at a cost of $20,000, in memory of his son and daughter, both of whom died from the disease. His wife and two sons are living, the latter being associated with their father in the business.

The Comstock-Castle Stove Company.

We are indebted to the Comstock-Castle Stove Company of Quincy, Ill., for a copy of their forty-fifth annual catalogue, covering the line of specialties which they manufacture. Within its colored paper covers attention is invited to new lines of coal and wood cook stoves and ranges, as well as a new line of Todd stoves. The company state that last year they made an extensive addition to one of their buildings and are keeping both foundries in constant operation, enabling them to promptly fill all orders with which they may be intrusted. The opening pages of the catalogue are devoted to an index, notices to the trade with regard to terms, freight, breakage, &c., as well as charges for drayage, loading and crating stoves. The opening pages are given up to the consideration of ranges, which are offered under such names as the Economy, a six-hole construction for hard coal, soft coal or wood; the Prize, a new six-hole stove, mounted on portable base and provided with draw and drop hearth top, patent oven door opener and other modern features; the Noxol, another addition to the company's assortment; the Magic Argand and the Eureka. Under the name Steel King the company offer a line of ranges intended for burning hard or soft coal. The body is made of cold-rolled sheet steel and the heavy castings of Bessemer iron. The oven doors drop upon bracket hinges, forming shelves capable of supporting, it is claimed, a man's weight. They are of sheet-metal, having Russia iron face and elaborately carved cast-iron mouldings and nickel-plated center panels. The cook stoves are shown in profusion, one of the recent additions to the line being the Prize Economy, a four-hole stove embodying the modern features and decorated in an attractive style. This is offered the trade in three sizes and the usual modifications. The Captain, Bessemer, Banker, Omega, Champion and Ardmore (the latter being a new four-hole wood stove,) are some of the other goods, to which attention is invited. The heaters occupy the latter portion of the catalogue and include the Economy, a richly treated Todd stove; the Antique Oak, which has been improved for this season; the Standard Oak, which is similar to the

heater just referred to, but has a somewhat cheaper finish; the North Star, a sheet-iron surface burner, made in two sizes; the Minnehaha, a well built surface burner; the Benjamin Franklin, a new parlor heater for hard or soft coal; the World's Argand, the Chime, the Bugle and the Prince, the latter being a two-hole laundry stove for any kind of coal. Several pages are given up to hollow ware and a list of stoves for which repairs can be furnished.

The Keokuk Stove Works,

with office and works at Keokuk, Iowa, have recently issued from the press an illustrated catalogue and price-list for the season of 1893–94. In offering this publication to the trade the makers call attention to their new specialties, which are known under the name "Ideal." These include cook stoves and ranges, as well as heaters, and embody the modern features of construction and decoration. The volume is composed of something over 70 pages of well-arranged matter, bound in colored paper covers. The leading place is given to the New Electric range, a well proportioned six-hole stove, in which has been incorporated the conveniences characteristic of first-class constructions. It is made in a variety of styles and sizes, several of which are illustrated. The Grand Ideal, a four-hole cook stove, made with broiler feed and also with pouch feed, for coal or wood; the Model Ideal, the National A2 and the National A3, the Family Ideal, the Home Ideal, the American, in various series, and the Surprise, a neat, cheap cook stove, are illustrated and described. The place of honor among the heaters is given to the Ideal Parlor, a neat surface burner for hard coal. It has draw center grate, large flues, anti-clinker grate, mica door, full-size fire pot and large oven in the top. The American Parlor, made in three sizes, for hard coal; the New American Oak, made in four sizes and embodying recent improvements; the Paros, a neat cottage parlor stove; the Ideal, a neat Todd stove for wood only, having heavy corrugated linings, nickeled and tile ornamentation, and the New American Oak, with hot-blast principle. This is claimed to be a very powerful heater and is offered in two sizes. A sectional view shows the manner of applying the ventiduct flue. A long line of cheaper goods, consisting of globe, cannon, laundry and cottage parlor stoves, are also shown, while hollow ware, a list of repairs and miscellaneous goods constitute features of the closing pages.

The Walker & Pratt Mfg. Company.

A stove catalogue measuring 9½ x 11½ inches in size has been received from the Walker & Pratt Mfg. Company of 31 and 35 Union street, Boston, Mass. The volume is printed upon a good quality of calendered paper, the engravings are well executed, clearly showing the features of decoration of the goods illustrated, while the binding is in paper covers, carrying a side title typographical in character. The goods to which attention is invited embrace a complete line of heating and cook stoves, steam boilers and radiators, hot-water heaters, steam kettles, hotel ranges and broilers, tea and coffee urns, carving tables, hotel cooking utensils, &c. In connection with each stove is presented ample descriptive letterpress, which calls attention to the special features of construction and ornamentation.

The first place in the catalogue is given to the Crawford Grand, a substantial six-hole range made in four sizes and the usual modifications. The Columbia is a richly treated six-hole range, the ornamental features being especially noticeable. It is made in four sizes, has large oven, ample fire box, sheet-iron ash pan and an arrangement of the bottom plate which prevents warping. Following this stove is the New World, which represents the company's latest addition to their line of specialties. This is slightly below the Columbia and the Crawford Grand ranges, as regards the hight of oven, but is well proportioned and equal in material and workmanship to the best goods turned out by the company. The treatment of the oven door involves the use of a bronze panel representing the landing of Columbus. The range is fitted with patented kindling damper, triple shaking grate, reversible pipe collar, sheet-iron ash pan and flues easy of access. Other goods include the Crawford, New Archer, Nelson, Palace, Eureka, the latter range being made for the use of wood only; Walker's nine-hole Atlanta range and the Franconia. A varied line of laundry stoves made under the name of Pyramid, is also shown, together with the Walker Equator, New England and Lakewood furnaces; the Laconia, Bowdoin and Good Cheer Franklin stoves; the Walker sheet-iron surface burner; the Railway King cannon stove; the Crawford and Commonwealth heaters, together with a line of farmers' boilers, water fronts, couplings, &c.

The Gem City Stove Mfg. Company

of Quincy, Ill., have sent us a copy of their annual catalogue of stoves, ranges and heaters. The printing is in red and black upon a good quality of white paper, and the binding is in paper covers with an attractive side title. Special reference is made to a number of the constructions illustrated in the catalogue, several of which have recently been added to the company's assortment. The leading place is given to the Golden Gem, a four-hole range of attractive design and fitted with ventilated oven, extra heavy covers, double and cut centers, large draw-out hearth, capacious ash pan and patent oven-door opener. The fire back is warranted to last for five years. In connection with the illustrations of the stoves are given descriptive particulars, dimensions and code words for ordering by telegraph. Another attractive novelty in the line of ranges is the Gold Gem, a four-hole construction embodying the modern improvements, and decorated in a neat manner. It is made in several varieties and is intended for burning wood only. Among the cook stoves we notice the Golden Gem, Art Gem, Eureka Gem and the Famous Gem, the latter being a four-hole cook for coal or wood, having large oven, capacious flues and cut and double centers. This is a well-made cook, and is offered at low price. A neat four-hole wood cook is the Art Gem, which is well made and mounted and offered in two styles. A varied assortment of heaters are presented, among which may be mentioned the Gem Starlight Todd, the Metal Oak, a first-class heater, with double fire pot for coal and single fire pot for wood, large bailed ash pan, and other features to commend it; Art Gem Oak, a member of the same class; the Handy Oak, a neat, cheap stove, made in two styles; the Ruby, a heavy cannon stove; the Coronet, a neat box stove, and the Knox, a neat laundry stove.

ODD PLATES.

As a sequel to the export note which appeared in our columns in the spring concerning the furnace to heat a portion of Kilwaughter Castle at Larne in Northern Ireland, we learn that the whole apparatus has arrived out, has been set up and worked excellently. Furthermore, finding there are two rooms in a distant part of the castle not provided for, the owner, J. Galt Smith, has written the manufacturers, Uzal Cory & Co., New York, to send another for this specific purpose, size 30 or 36, and all the necessary accessories, pipe, registers, &c., at once by Cunard steamer.

The Senate of the National Union held its twelfth annual session at the Hotel Cadillac, Detroit, last week, and in the afternoon of the first day of the meeting the delegates and their friends took carriages for the Michigan Stove Works, where they were treated to a collation and speech by George H. Barbour. After the visitors had inspected the extensive works of the company a drive was taken through the prettiest portions of the city and in the evening a reception was held in the parlors of the hotel.

Baker & Myers, wholesale stove manufacturers' agents, of Cleveland, Ohio, are distributing among their friends in the trade an illustrated circular of the four-hole cook stove made under the names Reliable Friend and Famous Friend. The former is provided with a base while the latter is fitted with legs only. The constructive features include Wilkinson's reservoir and closet, tin-lined oven-doors, heavy centers, patent oven-door kicker, solid or sectional fire back, lift-out ash pan, and supported long center. The stove is neat and attractive in appearance and is made for burning coal as a fuel. The firm have recently purchased the patterns of the Clifton cook stoves heretofore manufactured by the Canton Stove Company of Canton, Ohio, and will continue the production of castings from them. The firm state that they found that some of the patterns required changes, and where such was the case improvements have been made.

The Quick Meal Stove Company have had plans drawn for an addition to their factory, and bids for the construction are now being received. The addition will consist of a four-story building 55 x 125 feet, which will be made to harmonize with the other portion of the factory. The entire four floors will be used for manufacturing purposes.

A new folder, bearing testimony of the satisfaction derived from the use of heaters made by the Howard Furnace Company, Syracuse, N. Y., was recently issued by W. B. Wilkinson of the New York house at 210 Water street. Comparing it with the sheet used when he first became manager of this branch, it shows the Howard furnaces have been well distributed over his territory and used in some fine residences, increasing the popularity of their system of heating houses by hot air.

An Art Bay State Range of the '93 style is a late attraction in one of the Beekman street windows of the New

York house of the Barstow Stove Company. The beautiful luster it shows is due to "Blackene," which the house handle. One of the recent orders placed by them was for an assortment of 500 stoves and another for 150. Seventy Bay State Franklin stoves were recently sent out, showing that the deep lustrous black of Russia iron, when made into a heating apparatus, proves attractive.

W. G. SEMPLE shows some nice orders for the Clover Triumph and Mander Emblem ranges as the result of a few weeks' work among the builders in Philadelphia. These goods are made by the Philadelphia Stove & Iron Foundry Company of Philadelphia. The Belle Triumph is a handsome new portable range of medium price, and the Emblem is a larger range which has been redressed and furnished with skirting and top shelf.

F. H. MOORE, treasurer of the Howard Furnace Company, Syracuse, N. Y., recently spent a few days in New York on a business trip, finding time, however, to give *The Metal Worker* the pleasure of a call after he had visited their New York house at 210 Water street.

"PENINSULAR FURNACES" is the title of a pamphlet of nearly 50 pages which comes to hand from the Peninsular Stove Company of Detroit, Mich. The matter is made up of illustrations and descriptive particulars relating to the line of warm air and combination warm air and hot water furnaces which are made under the "Peninsular" name, and which are offered in a variety of styles and sizes. The reasons why these goods are considered the best are set forth in a comprehensive manner, while sectional cuts indicate the proper manner in which a Peninsular brick-set furnace should be installed. Numerous tables give price-lists of registers, cubic feet of air which pipes of various sizes will discharge per minute, together with dimensions of galvanized iron and steel, list of materials required when estimating in portable and brick-set furnaces, and a form of contract which is used by the Peninsular Stove Company.

CINCINNATI STEEL RANGE & FURNACE COMPANY, Cincinnati, Ohio, present a very attractive argument to the buyer in their line of Burton steel ranges. Those intended for use in residences have been designed to please the eye, and present many conveniences indispensable to the cook. For hotel and similar use, whether large or small capacity is needed, the Burton goods can be adopted to the requirements and location. A carving table, with dressing pots for four meats, consists practically of a small stove and a long tank. The stove has a water back for heating the water in the tank, which circulates and keeps the food warm, and the smoke, running under the tank to the end away from the stove through a flue, escapes to the chimney only after its principal heat has been given off to the water in the tank. Their steel laundry, for house use, has found general favor, and the demand keeps pace with the production. In their office a very novel ornament hangs on the wall in a frame with a glass over it. Considerable artistic ability has been displayed in arranging cuts of the early stoves made by S. H. Burton to form a pyramid, which is enlivened by the use of portraits from the fashion plates of the same day. These heads and busts are made to peep out from the ovens and fire chambers of the stoves, and with the coloring they contribute the effect is increased. At the top is a figure with the American flag as a proper climax to such a foundation.

P. BETTS, an experienced hot-air furnaceman, has elected the Columbian Vulcan as the heating medium of the day, and is visiting the trade in the interest of the Keeley Stove Company, Columbia, Pa., showing a new catalogue containing a line of furnaces which they think will fill every requirement.

THE COPPER GOODS AND COFFEE URNS of the John Van Range Company of Cincinnati, Ohio, have kept the manufacturing in that department going at a lively rate. Some contracts for fitting out hotel and restaurant kitchens have recently been closed, and among them is one for the restaurant of one of the principal railroad depots in their city. That these contracts will be filled with the Van Steel Ranges in their most approved form is a foregone conclusion, and the carving tables, plate warmers, pastry ovens and all of the utensils for the kitchen required by the experienced chef will be supplied by the same house.

"THIS BUILDING will be heated with the Novelty furnace and the Novelty ventilated wall pipe, furnished by J. P. Schaffer, 18 Wood street, Pittsburgh," is the information imparted by a neat sign on some of the finest buildings that are now being erected in that city. The wall pipe is something new that is just being brought to the attention of the trade, though it has been tested during the past winter.

W. B. WILKINSON, manager of the New York house, 210 Water street, of the Howard Thermostat Company, Syracuse, N. Y., has established an agency for their thermostats with August Eggars of Bremen, Germany. This is evidence that the wide scope of usefulness of the thermostat is extensively appreciated.

THE PITTSTON STOVE COMPANY of Pittston, Pa., are reported to have presented to the management of the new hospital in that place one of their handsomest Model Happy Thought ranges.

JAMES LAWRENCE, bookkeeper for Sam S. Utter, 111 Beekman street, New York, has returned from a well-earned vacation of two weeks. During that time he was sojourning among the woods and pines of Greenfield Hill, Conn.

EDWARD BENEDICT, treasurer of the Thatcher Furnace Company, has just returned from the Catskill Mountains, where he has been staying at his cottage at the Twilight Park. His stay was somewhat shortened owing to an urgent telegram calling him to the Thatcher Furnace Company's foundry, at Newark, N. J., to superintend the electric light plant that is being installed. A large number of heavy orders have been received from their Western agents.

THE DETROIT STOVE WORKS recently purchased a site, 200 x 112 feet, on La Salle street near Twenty-ninth street, Chicago, on which they propose to erect a warehouse for the storage of stoves. Plans have been completed for a five-story warehouse 100 feet square, which is to be placed under contract at an early date. The outer walls will be of pressed brick, and the interior will be of mill construction, being provided with elevators and other machinery for the expeditious handling of the company's goods. The offices and sample-room will be on the first floor. The company's offices and warehouse in Chicago are located at present at 269 and 271 South Canal street. When they remove to their new quarters the company will have the most southern stove house in Chicago, the others all being considerably further north. Expansion of business, however, demands better facilities, and locations are selected with that as the main object.

THE GENTLEMEN connected with the Chicago branch of the Michigan Stove Company enjoyed most hugely the trip on Lake Michigan in Commodore M. B. Mills' yacht "Grace" on the 15th inst. The day was perfect, making a cruise on the lake very acceptable as a refuge from city heat, dirt, noise and general discomfort. In addition, however, the Commodore spread an elegant lunch, providing refreshments of all kinds, which were most thoroughly appreciated. His liberality and constant desire to make others happy were strikingly shown in this entertainment, endearing him to the Chicago attachés of his great company. The occasion was one long to be remembered by those so fortunate as to be present.

THE WROUGHT IRON RANGE COMPANY, St. Louis, Mo., have just sold an entire kitchen outfit to a large hotel at Centerville, Iowa, also a large size Home Comfort double center range to be shipped to Mansfield, Pa., and a kitchen outfit consisting of Home Comfort Range and kitchen utensils to the Royal Albion Hotel, Quebec, Canada.

WE ARE informed that the following well-known stove houses have written to the World's Fair authorities declining to have their goods examined for premium or award: Rathbone, Sard & Co., Peninsular Stove Company, Buck's Stove & Range Company, the Michigan Stove Company, the Fuller-Warren Company, Cribben, Sexton & Co., Chicago Stove Works, Wm. Resor & Co., Orr, Painter & Co., the Collins & Burgie Company, Abendroth Bros., Thomas, Roberts, Stevenson Company, Co-operative Foundry Company of Rochester, Wm. Miller Range & Furnace Company, Estate of P. D. Beckwith, Richardson & Boynton Co., The Wilcox Water Heater Co. This comprises nearly all the American stove manufacturers exhibiting at the fair.

THE MICHIGAN STOVE COMPANY, through Frederic W. Gardner, manager, have made the following very liberal proposition to President Higinbotham of the exposition: "Under our 'Mammoth-Garland' in Section O, Manufactures Building, are shown the highest cost and highest finished Garland cooking range and heating stove ever manufactured. These we propose to donate for the benefit of the families of the firemen who lost their lives in the recent disaster, and it is our desire to dispose of them by lot, delivering the goods at the close of the exposition. It is our intention to realize several thousand dollars from the sale of tickets, and if this suggestion meets with your approval we request that you send us the proper authority to allow our representative to sell consecutively numbered tickets, the proceeds of which will be promptly turned over to you."

THE STOVE foundries of Canada are all at work now, writes a Canadian correspondent. The labor troubles that paralyzed production in so many of them last year are settled. But full operation is not an unmixed good. We have too many stove makers, and when their works are all busy there is a cer-

tainty that the total output will realize but a filmy profit, which some of the concerns will not be able to offset by economy of management and soundness of accounts. Already there are rumors of weakening in some quarters. Since the dissolution of the Association of Stove Founders competition has been waged pitilessly. Some of the makers within the association had got exasperated with the cutting of outsiders and when the association broke up the outsiders had more cause for regret than the insiders had.

ONE OF THE CUSTOMERS of the Thatcher Furnace Company, New York City, writes to them concerning the durability of the Thatcher furnace, stating that a heater placed in the boys' boarding school at Westchester, N. Y., in 1856, is still doing good service. It has been in use every winter for 34 years and there has been very little expense for repairs. Mr. Harrington, the principal, states that the furnace is economical of fuel and gives entire satisfaction. This testimonial letter is being used in advertising their business by St. John & Barquist of Des Moines, Iowa, who are agents for the Thatcher furnace.

THE SYRACUSE STOVE WORKS of Syracuse, N. Y., report that during the first six months of the present year they melted 350 tons of iron more than for the corresponding period of last year, and that the quantity of stoves shipped for the period named showed an increase over that for 1892 of 200 tons. The business in repair castings for the past six months also showed a gratifying increase over that a year ago. From this increase of the manufacturing department, we understand that there was a gain in the volume of business amounting to something like $20,000. Since starting up early in the year the company have run continuously and hope to give steady employment to their force of 100 men during the remainder of the year.

THE CHICAGO & ERIE STOVE COMPANY of Erie, Pa., have introduced into their Brilliant Helper a number of improvements which are likely to prove interesting to the trade. The stove has a large circulating hot-air flue which takes the cold air from the floor and discharges it in a highly heated condition from the top, while by means of a collar and adjustable damper a hot-air pipe may be connected in such a way as to carry the heat to the floor above, thus making the stove serve as a double heater. The Brilliant Helper, which is offered to the trade this season with new base, new rails and new back, is neat in appearance, the decoration involving the use of nickeled parts, which are judiciously disposed.

THE WALKER & PRATT MFG. COMPANY of 31 and 35 Union street, Boston, Mass., are distributing several eight-page circulars relating to Walker's New World six-hole, Walker's Columbia and Walker's Crawford Grand ranges. These stoves are carefully illustrated and fully described, special reference being made to the important features of merit.

DAVID U. CORY of Englewood, N. J., has recently been granted a patent for a damper so constructed as to form a ventilating opening in a pipe or flue, and at the same time to cut off the pipe so that the gases conducted thereby cannot escape into the room. Heretofore it has been the common practice to construct furnace or stove-pipe dampers with ventilating openings above and below the damper spindle, which ports or openings were closed by segmental covers which rotated with the spindle. By this means ventilation from without to within the pipe could be effected through the opening above the damper spindle, but the gases of the flue could escape from the pipe through the opening below the damper, and the object of the invention is to obviate this and allow of ventilation while preventing the gases from flowing into the room.

Prize Competitions.

THE COMMITTEE to whom the papers in Prize Competition No. 19 were referred have awarded the prizes to the following persons:

First Prize to W. P. STEWART.
Second Prize to W. E. GILL.
Third Prize to W. F. VAN WINKLE.

Export Notes.

A reliable firm of exporters, who ask no credit, recently had in hand orders for about 12 carloads of Galvanized Sheet Iron, suitable for roof tiling, which is coming more and more into use in Spanish America. The greater portion of this is still unplaced.

One of the aggravations of export merchants is to write a manufacturer for quotations on specific goods and quantities, and have him answer in two or three different communications he does not see how he can compete in his line with foreigners. If the house ordering understand their business it is not necessary for him to see it. That part of the transaction they have been studying both in this and foreign markets, while the manufacturer has mainly confined himself to producing goods. Many conditions have recently changed in this respect. An instance applicable to many cases came to our notice lately. A mill rolling metal for sheathing, out West, sent out not long ago a sample lot, which, proving satisfactory, was quickly followed by a second requisition equal to the amount of the first multiplied by itself, aggregating about $1000, with the prospect of an increasing business. This opportunity was missed by a concern too cautious to try, where very little was involved in the experiment.

There is a company in this city who have shipped 1000 tons of Sheet Metal since January 1, 1893, to a market that has been open to us on these goods but a year, and which was formerly supplied largely from Great Britain.

A good story illustrative of the merit of some American goods in European markets is told by a merchant who has for years placed large quantities of our products in great Britain. An English manufacturer of Pumps gave an order for a sample lot of W. & B. Douglas' goods some years ago, which was executed, and, be it said, was the only order given. Within a comparatively short time those identical goods were duplicated by him, but stamped "Colonial," on which a large local as well as Australian, &c, trade has been built, the trade continuing at the present time. Benjamin Douglas being in England some time after drifted into an agricultural fair in one of the towns and was attracted by an exhibit of Pumps, which proved to be identical with the "Colonial" pattern, but the closest scrutiny failed to discover the trade name under which the goods were being sold. His suspicions being aroused he became more critical and finally discovered where the "W. & B. Douglas" cast in the goods had been removed and the Pumps refinished. Mr. Douglas' remark to his agent was that it was revenge enough for him, partially reconciling him to loss of considerable trade, that an English maker was exhibiting his (W. & B. Douglas') goods for the purpose of capturing a medal at a county fair.

A Novel Profession.

The host of labor disputes which have marked the past few years in England, and the great loss and inconvenience attendant upon strikes, have caused the evolution of a new profession in that country. There has arisen a class of leaders men, termed "strike defeaters," whose business is that of breaking down strikes, not by physical or military force, but by the more peaceful method of doing the work of the strikers until they come to terms. One of the most prominent of these individuals, whose name is Graeme Hunter, is described as a powerful, energetic man in mind and body, who lives with his men, but rules them with strict discipline. His methods are in some respects peculiar, and appear slightly arbitrary to an American mind. As described by English journals, Mr. Hunter's system is as follows: He has the reputation of never interfering in a strike until all means of settling it have been exhausted and he believes the strikers to be in the wrong. Then he simply puts his men to work and keeps them at it. He tells his hands how much he gets to do the job, and the way he makes his own remuneration is by simply dividing the whole amount among them according to their labor, less 1 penny out of every 5 shillings they earn, over and above the expenses incurred. He has under his control some 3200 men, whose average wages are about $6 a week, besides board and lodging. They are all obliged to live together near to where they may be working, and Mr. Hunter insists on every married man sending home at least £1 a week to his wife, paying them this amount in postal orders, collectible at the home of the wife. Fines are exacted far the absence from work, &c., and no recognition of union rules is had. It is said that eight of his gangs were recently employed at eight ports, including Liverpool, Glasgow, Greenock, Dublin and Bristol, by which it would seem that these men are all-round laborers and not skilled workers.

Gas consumers often complain that books, furniture and pictures are injured by the small quantity of sulphur which, despite all precautions, passes through the burners. But, says a London gas journal, Dr. Odling, F.R.S., and Professor Lewis, two British experts, in giving evidence before a committee on the Crystal Palace Gas bill, declared that this idea was an error. The damage was not due to the sulphur, but to the heated zone of the atmosphere above the chandelier. Dr. Odling produced a sulphur candle such as is used for disinfecting purposes, and this he observed would exercise no injurious effects upon furniture. When, however, it was suggested that it should be lighted in the committee room in order that members might appreciate its effect the idea was not taken up with scientific eagerness.

TRADE REPORT.

The Iron Market.

From all parts of the country come the reports of stagnation in the Iron business, and evidence is not wanting that even with the heavy restriction in production the supply overbalances the demand. Forced sales occasionally crop up, and low prices might be more frequently made if there were buyers able and willing to grant favorable terms of payment.

That there are those who have the courage to contract heavily in these critical times is proved by the fact that a Chicago implement manufacturer has bought from a leading Pittsburgh mill 28,000 tons of Steel Bars, for a year's delivery. Other implement makers have also bought or are negotiating.

The restriction in the make of Pig Iron is proceeding, and four large Pittsburgh furnaces are to be added soon to the idle stacks.

There seems no immediate chance for a settlement of the wages scale. The logic of events is decidedly against the men, who have declined to make any concessions on finishing applicable to the great majority of the Western mills. A sliding scale which slides only down to a 2-cent basis for Bars, when the actual selling price is 1.40¢, is a farce.

Pig Iron.—In New York the market is very dull, but for standard brands prices are well maintained. We quote Northern brands at $14.50 @ $15 for No. 1; $13.75 @ $14.50 for No. 2; $12.25 @ $12.50 for Gray Forge, at tidewater. Southern Iron, same delivery, $13.75 @ $14.50 for No. 1; $12.50 @ $13.50 for No. 2; $12 @ $12.25 for No. 3; $12.25 @ $12.50 for No. 2 Soft, and $12.75 @ $13.25 for No. 1 Soft. Gray Forge remains $11.75 @ $12.50.

The Philadelphia market is reported as dull, and while there is no great pressure to sell, the outlook is far from encouraging. The severe curtailment of production obviates any serious accumulation of stocks, which is probably the only thing that could be done to avoid disaster. The supply of good Iron is not large and prices are steady, with little chance of their going any lower. Meanwhile the demand is for small lots, for which prices are as near the figures quoted below as circumstances will permit, although for spot cash concessions of 50¢ ℔ ton have been made, and in some cases still heavier concessions have been met with, particularly on secondary qualities of Iron. Ordinarily, however, asking prices for Philadelphia and near-by points are about as follows:

American Scotch, No. 1X	$16.00	@	$16.50
American Scotch, No. 2X	15.00	@	15.50
Standard Penna. (Lake Ore), No. 1x	15.00	@	15.50
Standard Penna. (Lake Ore), No. 2x	14.00	@	14.50

The Pittsburgh Market is at a standstill. Although production shows a large falling off consumption has at the same time declined to even greater proportions and the outlook is regarded as very unpromising. Prices have, nevertheless, been fairly steady, although a good order placed now might shade the lower quotation. Quotations are as follows:

No. 1 Foundry	13 50	@	13.75 "
No. 2 Foundry	12.50	@	12.75 "
Charcoal Foundry No. 1	17.00	@	18.00 "
Charcoal Foundry No. 2	16.50	@	17.00 "

Chicago advices report an equally dull trade. Very little Iron is being shipped from furnaces to consumers, showing that consumption has dwindled to almost nothing. Inquiries are light, and negotiations which seemed quite promising a week ago are not materializing. Conditions have grown worse instead of better, and there seems to be no early prospect of an improvement. The following quotations are conditioned as the nearest obtainable expression of values, but they would be shaded in case of actual transactions:

Lake Superior Charcoal	$16.00	@	$16.25
Local Coke Foundry, No. 1	13.50	@	14.00
Local Coke Foundry, No. 2	12.75	@	13.00
Local Coke Foundry, No. 3	12.50	@	12.75
Local Scotch	14.00	@	15.00
Ohio Strong Softeners	15.75	@	16.25
Southern Silvery, No. 1		@	14.50
Southern Silvery, No. 2		@	14.00
Southern Coke, No. 2	12.75	@	13.00
Southern Coke, No. 3	12.25	@	12.50
Southern, No. 1, Soft	12.65	@	13.00
Southern, No. 2, Soft	12.25	@	12.50
Southern Gray Forge	11.50	@	12.00
Tennessee Charcoal, No. 1	16.50	@	17.00
Alabama Car Wheel		@	18.85
Coke Bessemer	14.50	@	15.00
Hocking Valley, No. 1	16 75	@	17.00
Jackson County Silvery	16.75	@	17.00

There has been a restricted volume of business in Pig Iron during the week in Southern markets, and no relief from the prevailing financial stringency has yet been experienced. The market is generally so demoralized that nearly every transaction has an independent basis, and it may be assumed that where the cash is in sight it brings the Iron at the lowest prices. There have been sales during the week, mainly in single car lots locally delivered, and nearly all kinds of Iron were taken, except Standard Charcoal Iron. Quotations as follow nearly represent the current rates prevailing on Southern Pig Iron:

Foundry.

Southern Coke, No. 1	$12.75	@	$13.00
Southern Coke, No. 2	11.25	@	11.50
Southern Coke No. 3	10.75	@	11.00
Ohio Soft Stone Coal, No. 1	15.50	@	16.00
Ohio Soft Stone Coal, No. 2	14.50	@	14.75
Lake Superior Coke No. 1	15.00	@	15.25
Lake Superior Coke No. 2	14.00	@	14.25
Hanging Rock Charcoal, No. 1	18.50	@	19.00
Hanging Rock Charcoal, No. 2	17.50	@	18.00
Tennessee and Alabama Charcoal, No. 1	14.75	@	15.00
Tennessee and Alabama Charcoal, No. 2	13.75	@	14.00

Forge.

Gray Forge	10.25	@	10.50
Mottled Coke	10.25	@	10.50

Car Wheel and Malleable Irons.

Standard Southern Car Wheel	16.75	@	18.00
Lake Superior Car Wheel and Malleable	17.25	@	17.50

Metal Market.

Pig Tin.—Speculation has been on a smaller scale, and the market has shown weaker tone in the face of steady reduction in the stocks here. General financial uncertainty has a more or less unfavorable bearing and offsets what strata of strong feature there may be in the position of the market. Prices have dropped to 18.75¢ for spot delivery, 18.90¢ for August, and 19.30¢ for September, a decline of over ¼¢ ℔ lb during the week. Upon the whole the market shows a weakness which clearly indicates that best efforts to sustain prices are offset by the financial depression which prevents unloading of the usual amount of Tin from first hands into the channels of distribution and consumption. Consumption, too, has been undoubtedly checked under the same influences to a considerable extent.

Copper.—The market has remained very quiet, and is bare of distinctly new features, except that it seems easier to buy at prices that looked exceptionally low last week. Demand from home consumers does not improve perceptibly, and, if anything, the market is showing a rather weaker tone. Current quotations are about 10¼¢ for Lake Superior Ingot, although bids for a fraction less were made on the exchange, and an offer of 10.15¢ for September delivery found no takers. Electrolytic, 10¢; Common Casting stock, 9¾¢ @ 9⅞¢.

Pig Lead.—Under continued pressure to sell prompt and near future delivery, prices have declined still further and the market remains in very unsettled condition. Early in the week several hundred tons were sold at 3.50¢, moderate quantities went subsequently at 3.45¢, and finally some good-sized lots at 3.40¢.

Spelter.—Slow demand, along with continued pressure to sell, have caused a further decline in prices and the market remains in very weak condition. Ordinary brands of Western were sold

at 3.95¢ @ 4¢, in carload lots, and those figures reflect full market value at the present time.

Antimony.—There is only a moderate inquiry and prices are barely steady at 9¾¢ @ 9⅞¢ for Hallett's, 10⅛¢ @ 10¼¢ for L X, and 10⅜¢ @ 10½¢ for Cookson's, on the spot.

Tin Plate.—The demand has shown little, if any, improvement and the tone of the market for both spot stock and future deliveries continues rather weak, with concession from the prices generally quoted not infrequent. In Ternes there is, however, some little movement noted, owing to requirements of the building and roofing trades, but orders are usually for limited quantities, no one being apparently desirous of laying down any considerable stock under present uncertain conditions in regard to financial and tariff legislation. The bulk of the demand for roofing Tin will, it is thought, set in a month or two later; and a good fall business in this line is generally anticipated. For Bright Plates the immediate demand is next to nothing. Stocks are large and the assortment full in both imported and domestic material, and cash orders would likely meet with some shading of the prices generally asked.

Chicago Report.

Scrap.—The following buying prices are still quoted by some dealers, but most of them are refusing to take in any stock, because consumers are doing nothing:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$10.00	....
Machinery Cast	7.50	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	5.00	....
Burnt Iron and Grate Bars	4.00	....
Sheet Iron and Hoops	3.00	....
Plow Steel and Breaking Stock	6.00	....
No. 2, such as Shovels, Hoes, &c	4.50	....
Old Boilers—whole (Iron)	6.00	....
" (Iron)—cut in single Sheets and Rings	9.00	....
Old Gas-Pipe and Boiler Tubes	6.00	....
Cast Borings	3.50	....
Turnings	5.00	....
Horseshoes	10.00	....
Copper Bottoms	....	7 ¢
Copper Clips and Heavy	....	8⅛¢
Heavy Brass	....	7⅛¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2½¢
Zinc	....	2¾¢
Rubber	....	2¾¢

Anthracite.—Trade is still extremly dull. Dealers quote carload lots of 12 net tons as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9 30

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

CONDITION OF THE

Hardware Trade.

THE INACTIVITY IN BUSINESS which has prevailed since the opening of the month still continues and the volume of trade is small. Jobbers are refraining from pressing sales, and are scrutinizing credits carefully. They are also deferring the placing of their usual orders, and in some cases where their orders have been booked have recently been writing to the factories countermanding portions of the orders or postponing shipments for a few weeks. They are thus evincing a disposition to await the developments of the market, their principal attention being given to collections and financial matters. Manufacturers are pursuing a similar course, and while in many cases curtailing production and carefully avoiding the accumulation of goods, are generally conservative in the marketing of their products and maintaining prices pretty well. In some cases, however, concessions have been made, for the most part, it is thought, under the pressure of financial necessity, in order to realize upon goods in stock. The close prices which have been prevailing on most lines of Hardware prevent the manufacturers, however, from lowering their quotations without incurring actual loss. Retailers also are feeling the stringency in the money market and diminished sales in some sections, owing to the closing of shops and factories, and are buying very sparingly, their orders covering limited assortments of goods of which they are in need. In the present condition of things the trade, both wholesale and retail, are apparently pursuing the policy of keeping their stocks as low as possible, expecting to place their orders when the fall demand sets in. They are thus relying upon the manufacturers to carry the stocks of goods to a greater extent than usual, while the manufacturers, as noted above, are prudently endeavoring to avoid an undue accumulation. The result of this policy will be the production of a considerably smaller quantity of goods than is usual, and if a considerable demand should suddenly set in something of a scarcity might occur. The trade, however, prefer to take their chances in this matter rather than load up with goods, in the payment for which and subsequent sales they might experience some difficulty. Collections are difficult and only houses who are in an especially favorable condition are availing themselves of cash discounts. There are, however, some indications of improvements in the matter of remittances.

Advices from Chicago.—The condition of the Hardware trade remains about as stated last week, with trade stagnant but collections steadily working into better shape. Jobbers are reducing expenses in every direction, and are doing very little to force trade, as they are of the impression that it is advisable now to sell only to those who are in need of stock and are able to pay for it. The failure of Parkhurst & Wilkinson of this city, which occurred on Monday, takes down one of the largest and oldest Heavy Hardware houses in the Northwest, whose name has been respected throughout the trade and is synonymous with fair dealing and honest goods. They have the sympathy of the entire trade in the misfortune which has befallen them. Their early resumption is expected, as it seems unreasonable that they will not be able to effect some arrangement with their creditors.

Notes on Prices.

Cut Nails.—Some of the Cut-Nail mills are still in operation, though working on short time and with considerably diminished output. Others, and among them some of the leading ones, are shut down. An accumulation of stock is thus avoided, though there is no difficulty in having orders promptly filled. Prices are pretty well maintained on substantially the same basis as for the past few weeks, namely, $1.05 for carload lots at mill, a figure which is shaded for Iron Nails, and also in some special cases on Steel Nails. Small lots from store in New York are quoted at $1.30. The demand is sluggish and the volume of business small.

Advices from Chicago.—The Steel-Nail factories are still closed, but there appears to be no difficulty in supplying the trade with all the Nails wanted from stocks carried over in their warehouses. The demand is of such a character that most of it runs to less than carloads. Prices from factory are unchanged at $1.20 to $1.25 and from store at $1.25 to $1.30, according to quantity.

Wire Nails.—Notwithstanding the fact that the mills have been closed during the month, there is no difficulty in the trade obtaining such Nails as they require, even though it is understood that the stocks in manufacturers' hands are not heavy. Quotations are more evenly maintained than for some time past at $1.35 for carload lots at mill, and the manufacturers are indisposed to shade this price. The question as to what can be done by the manufacturers to give regularity to the market is receiving attention, and some of the manufacturers express confidence that something may be accomplished in this direction. The present unsettled con-

dition of things in the market at large, and the fact that business of late under the very active competition which has existed has been decidedly unsatisfactory, have their influence in overcoming some of the objections which have been entertained by some of the prominent manufacturers to such an arrangement. While nothing definite has as yet been consummated it is regarded as more probable than heretofore that some satisfactory conclusion may be reached, notwithstanding the fact that serious difficulties still remain.

Advices from Chicago.—The only demand experienced by manufacturers is for shipments of carloads to scattered buyers throughout the country, the demand generally being extremely light. Stocks are reported low in manufacturers' hands, consisting of only about 100,000 kegs, and they are buying from each other, but so trifling is the demand at present that such a stock would seem to fill their requirements for weeks to come. The manufacturers held a meeting last Wednesday and hold another this week to endeavor to perfect a plan to improve the condition of the Wire-Nail trade. All are interested except the Carnegie Steel Company, and the prospects are reported bright for an agreement upon the limitation of output to the exact wants of the country. The manufacturers express themselves as being so disheartened over results of the past three months that they are ready to unite with one another upon any reasonable basis which may promise to relieve the situation. The factory price is unchanged from $1.45 Chicago, while small lots are selling from stock at $1.55 to $1.60, according to quantity.

Barb Wire.—The Barb-Wire market is stagnant. Quotations remain as before at $2.45 to $2.50 for carload lots of Four-Point Galvanized, at mill. Small lots from store are held at the usual advance.

Advices from Chicago.—Trade in this line is absolutely neglected. Hardly a transaction is heard of in any direction. Prices are unchanged at $2.10 for carload lots of Painted, and $2.50 for Galvanized, while small lots from jobbers' stocks are quoted at $2.30 and $2.70 respectively.

Oil Cans.—Youngstown Stamping Company, Youngstown, Ohio, are selling their Galvanized Blue Band and Glass Oil Cans at the following prices:

	Per dozen.
Galvanized Blue Band Can, 5 gallon, Tip-Top	$12.00
Galvanized Blue Band Can, 5 gallon, Faucet	8.00
Galvanized Blue Band Can, 1 gallon.	2.25
Friend Glass Oil Can	2.75

Blocks.—The Cleveland Block Company, Cleveland, Ohio, have reduced the price of their Blocks, their present quotations being represented by discount 60 to 60 and 10 per cent. They also advise us that they have decided not to adopt a soft-steel shell for their Blocks, though somewhat less expensive, referring to the rope as liable to cut through it, leaving a sharp edge, which is not the case with their malleable shells.

Glass.—As is usual with the Glass market at this season trade is quiet and there have been no changes either in demand or prices since our last report. Meetings of the National Glass Company and the Glass workers were held last week, the manufacturers meeting in Chicago and the workers in New York, at which the questions relating to scale were discussed at some length. Committees representing the manufacturers and their employees will soon come together, but the date has not yet been definitely determined. A meeting of the stockholders of the National Glass Company was held in Chicago on July 25, at which a statement was presented outlining the work of the company during the fire just closed. The plant of the Pennsylvania Plate Glass Company has resumed operations, but it is not thought likely that this action on their part will induce other concerns to follow their example. The company are paying former rates, having failed to effect the 10 per cent. reduction in wages which they contemplated. The slight improvement in demand for imported Glass noted last week continues, and we understand that a few large orders have been placed. Quotations on Glass remain unchanged, as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—Prices are fairly well maintained at present rates, with a minimum amount of business doing. The following are the prices paid for Old Rubber delivered in New York, except as otherwise stated:

Car Springs, ton lots, ℔ lb.	@	$0.03¼
Rubber Shoes, carloads, delivered at factory, ℔ lb.	@	.03⅛
Rubber shoes, less than carloads	@	.03
Large Hose, ℔ ton	@	9.00
White Wringer Rolls, ℔ lb.	@	.04¼
White Wringer Rolls, good grade	@	.05
White Syringes, ℔ lb.	@	.05

Old Rags, Paper, &c.—Business in this line is practically at a standstill, no one knowing exactly what to do. Buyers seem to be holding out for lower prices, while sellers, where able, seem to prefer holding on for more favorable rates. As many Paper mills have shut down, or are running on reduced time, there is naturally not the demand there has been. Many dealers who usually carry stocks to meet a demand are not buying, on account of inability to sell promptly. The following are the current prices quoted for Old Rags, Paper, &c., delivered in New York:

No. 1 White Rags	℔ lb 3	@ 3⅛¢
No. 2 White Rags	℔ lb 2	@ 2⅛¢
Mixed Rags	℔ lb	1¼¢
Blues and 3ds	℔ lb	1¼¢
Hard Sized White Shavings	℔ lb	2⅜¢
No. 1 White Book Shavings	℔ lb 2¼	@ 2⅜¢
No. 2 White Book Shavings	℔ lb 1½	@ 1⅝¢
Light Book Shavings	℔ lb ⅞	@ 1¢
No. 1 Mixed Shavings	℔ lb	1¢
No. 2 Mixed Shavings	℔ lb	⅝¢
No. 1 Printed Books	℔ lb 1	@ 1¼¢
Ordinary Mixed Books	℔ lb ½	@ ¾¢
Newspapers	℔ lb	⅝¢
No. 1 Manila Paper	℔ lb 1¼	@ 1¼¢
No. 2 Manila Paper	℔ lb ⅞	@ 1 ¢
Bogus Paper	℔ lb ⅝	@ ¾¢
Common Paper	℔ lb ¾	@ ⅞¢
Straw Chips	℔ lb ½	@ ⅝¢
Binders' Clippings	℔ lb ½	@ ⅝¢
Jute Butts	℔ lb	1¼¢
No. 1 Jute Bagging	℔ lb 1¼	@ 1⅜¢
Mixed Bagging	℔ lb	1¢
No. 2 Bagging	℔ lb	¾¢
Hemp Twine	℔ lb	2¼¢
Manilla Rope	℔ lb	2¼¢
Jute Rope	℔ lb 1½	@ 1⅝¢
Mixed Rope	℔ lb ¾	@ ⅞¢

Old Metals.—The trade in this class of goods is almost at a standstill, many dealers preferring their goods to an account. As for prices, it often depends on how badly a dealer wants to buy or sell what basis is determined on to close a transaction. Some are doing next to nothing, preferring to sit still and await developments. The following are fair quotations now current for Old Metals in New York, subject to the conditions stated:

Heavy Copper	℔ lb 9½¢
Light and Tinned Copper	℔ lb 8½¢
Heavy Brass	℔ lb 7¢
Light Brass	℔ lb 6¢
Lead	℔ lb 3½¢
Tea Lead	℔ lb 3½¢
Zinc	℔ lb 2¾¢
No. 1 Pewter	℔ lb 14¢
No. 2 Pewter	℔ lb 7¢
Wrought Scrap Iron	℔ gross ton, $13.00
Heavy Cast Scrap	℔ gross ton, 9.00
Stove Plate Scrap	℔ gross ton, 6.00
Burnt Iron	℔ gross ton, 4.00
Mixed Bagging	℔ lb 1 ¢
No. 2 Bagging	℔ lb ¾¢
Hemp Twine	℔ lb 2½¢
Manila Rope	℔ lb 2¼¢
Jute Rope	℔ lb 1⅞ @ 2 ¢
Mixed Rope	℔ lb ¾ @ ⅞¢

Trade Notes.

THE WILLER MFG. COMPANY of Milwaukee, Wis., have issued an advertising sheet showing a general view of the Marion High School building at Marion, Ind., which is furnished throughout with the Willer Sliding Blinds. Below the picture of the building are photographic copies of the letters received from the president of the school board at Marion, Ind., and also from the contractors and architect of the building.

THE MICA MFG. COMPANY (John O'Neill, proprietor), 89 Fulton street, New York, issue a little pamphlet of a size convenient to carry in the pocket, relating to Mica, Mica goods and specialties. Attention is invited to the line of Mica Protectors for Lamp Shades, which are made in several sizes and adapted for all kinds of shades. All the canopies, except smoke bells,

have screw tops, which, the company state, render them more durable The little pamphlet is illustrated, showing the appearance of the various Mica specialties manufactured, while tables give the retail prices of Mica by the sheet.

BLESS & DRAKE, Newark, N. J., make a specialty of the manufacture of Sad Irons in great variety and tailors' Geese. Their leader is the Ideal Sad Iron with a detachable wood handle. Self-heating smoothing and tailors' irons are made in several patterns. In 24 hours pig iron is changed into the finished product and ready for shipment, several tons being used daily and about 100 men are employed. Grindstones weighing 2 tons and 6 feet in diameter, with a 12-inch face, are run at a high speed for grinding, while the polishing is done by fine emery or special wheels.

ILLINOIS ROOFING & SUPPLY COMPANY, 203 Lake street, Chicago, make a prominent announcement elsewhere in this issue directing attention to the Perfection folded lock-seam steel roofing, the advantages of which they note. They guarantee the roof and request that it be returned at their expense if not found as represented. They also refer to "E. L." roofing tin, which they describe as an American coated terne of full Worcester grade.

"THE HUSTLER" is the title of a publication sent us by the National Cash Register Company, Dayton, Ohio. It is a very elaborate trade circular, the front page being printed in colors with very handsome effect. The back of the circular gives a bird's-eye view of the factory of the company, together with views of several of their registers, and the interior pages contain the names of many people using these devices. The circular comes to us with the compliments of E. D. Gibbs, the advertising editor of the company.

POWERS BROTHERS, Streator, Ill., are meeting with an excellent demand for Powers' Patent Automatic Chimney Top of their manufacture. They are selling these largely to the jobbers and hardware dealers, and particularly note that the tops are put up in a very compact manner, so that dealers can carry them in stock without taking up much room. The iron mountings are packed six sets complete, with patterns for making the cover and vane, in wood boxes about 10 inches square. The iron mountings are made so that there is only one bearing and all the friction is next the cover, while there is a brace at the bottom of the cover to hold it in position and keep it from rubbing against the stack or becoming loose.

LALANCE & GROSJEAN MFG. COMPANY, New York, closed down their factory at Woodhaven, L. I., for the current week on account of the dullness of trade and the large stock of finished goods on hand, as well as for the purpose of making certain repairs and a general overhaul. The factory will resume operations next Monday, closing down again for the following week, subsequent to which the company propose running the works right along, as usual, should the condition of business justify them in doing so. This arrangement has been made out of consideration for the workpeople in order that they may not be without wages for two consecutive weeks.

THE PLANT of the W. Dewees Wood Company at McKeesport, Pa., manufacturers of patent planished sheet iron, which has been undergoing repairs since June 30, has resumed operations in all departments.

THE FIRM OF C. C. CLAPPER & CO., Zanesville, Ohio, dealers in Hardware, Harness and Buggies, has been dissolved. C. C. Clapper will continue the business at the old stand.

C. S. OSBORNE & Co. of Newark, N. J., exhibit, at the World's Fair, Chicago, two large showcases, filled with specimens of their Standard Saddle and Harness Tools, beautifully nickel plated. All kinds of tools are shown which are used in the saddlery and harness trade, including Cutlery, Marking Tools, Punches, Rosette Punches, Pincers, Eyelet Machines, Hammers, Screw Drivers, &c. They also exhibit specimens of their Upholsterers' Tools, Nut Cracks, Gas Pliers and miscellaneous tools. Evidently as much care has been taken in finishing the handles of these tools as in making the tools themselves. The display is exceedingly creditable throughout.

MATTHAI, INGRAM & Co., Baltimore, Md., have completed a new department for galvanizing and an additional fire-proof building for retinning, which will give them facilities, they advise us, equal to any concern in the country. They will soon occupy the structure built on the site of their fire in march, and expect to add new lines of desirable goods.

A LINE of stamped and pieced tinware made out of the Dunlap double dipped tin-plate, which includes several specialties, makes the John Dunlap Company of Pittsburgh one of their own customers for their own production of bright tin plate, while the trade at large are making increased demand for both bright and roofing plates.

MAHER & FLOCKHART, Newark, N. J., who do a general foundry business, have recently added to their plant a new cupola from the Detroit Foundry Equipment Company, Detroit, Mich.

THE DETROIT FOUNDRY EQUIPMENT COMPANY, Detroit, Mich., have opened an office in New York at 182 Front street, in charge of J. Gilmour, who has had experience as a foundry superintendent with the Pittsburgh Locomotive Company and with Uzal Cory & Co.

F. A. SMITH is making a few days' stay in New York looking after the interests of the Wm. H. Page Boiler Company of Norwich, Conn., among the dealers in steam and hot-water apparatus in this vicinity.

THE NIAGARA RADIATOR COMPANY have been organized with a capital of $120,000, and may locate a plant for the manufacture of radiators at Tonawanda, N. Y.

There lives a "carpenter" we wot of, says an English exchange, not 100 miles from London, who announces that he "repairs locks, lamps, and furniture," does "soldering, plumbing, glazing, and coppersmiths' work," "mounts and finishes in any design repoussé brass-work," "grinds by new and improved machinery scissors, knives and forks," "repairs and enamels cycles," "takes inventories," and sells "oils for burning and lubricating." This is, we should say, a *bonâ fide* Jack-of-all-trades. Where do the other tradesmen come in?

The telephone is now being used by divers. While at the bottom of the water they can thus communicate with those in charge of the apparatus above, and receive instructions as the work proceeds.

It Is Reported—

That Vensel & English's Hardware store at Butler, Pa., was recently damaged by fire. Loss, $7000; insurance, $2500. A. W. Root's Hardware, store was also damaged, the loss being about $2000, with no insurance.

That Thomas Newall has disposed of his Hardware store at Carterville, Mo., to Eli Keller of Webb city.

That the Hardware store of Young, Tuttle & Company, North Berwick, N. H., was burglarized on the 12th inst.

That B. K. Northrup will soon open a new Hardware and Stove store at Westport, N. Y.

That burglars visited the Hardware store of Baldwin Bros., Lincoln, Neb., on the 4th inst. and got away with a quantity of Razors and Shears.

That Charles Cutler, a Hardware merchant of Baldwin, Kan., was seriously injured while returning home from Lawrence. A runaway team dashed into his light buggy from the rear and completely wrecked it. Mr. Cutler was thrown to the ground and trampled upon by the team. His head was crushed on one side, his body bruised and his back badly wrenched. His condition is serious.

That the Hardware store of Stronk & Le Page, Baldwin, Wis., was broken into by burglars on the 7th inst. and $200 worth of Cutlery stolen.

That in a fire at Des Moines, Iowa, on the 5th inst., the Hardware stock of J. A. Garver & Co. was damaged by water to the extent of $9000.

That burglars entered the Hardware store of J. W. Seaman, Washington, Pa., on the 6th inst. and got away with $75 worth of stock, including Revolvers, Razors, Guns, &c.

That John N. Maute will soon erect a large Hardware store on Central avenue, Lancaster, N. Y.

That William Chamberlain has opened a new Hardware store at Dorchester, Mass.

That the Hardware store of Jater & Dixon, Russiaville, Ind., was destroyed by fire on the 6th inst. Loss, $7000.

That L. E. & E. E. Guignon's Hardware store at Corry, Pa., was damaged by fire on the 7th inst.

That burglars broke into the Hardware store of T. O. De Jean, Plankington, S. D, on the 14th inst., and secured some valuable plunder.

That Robert Malstrom's Hardware store at Lake City, Minn., was burglarized on the 14th inst. and $150 worth of goods stolen.

That T. J. and S. Ulen, Hardware merchants, Dexter, Mo., have sold out, Miller, Riddle & Co. continuing.

That the Robert Donahue Iron and Hardware Company, Burlington, Iowa, have filed articles of incorporation. The capital stock of the company is $75,000, of which $65,000 is paid up. The officers are: Robert Donahue, president and treasurer; Geo. Donahue, vice-president and Albert Cobworth, secretary.

Current Hardware Prices.

JULY 28, 1893.

Note.—The quotations given below represent the Current Hardware Prices which prevail in the market at large. They are not given as manufacturers' prices, and manufacturers should not be held responsible for them. In cases where goods are quoted at lower figures than the manufacturers name, it is not stated that the manufacturers are selling at the prices quoted, but simply that the goods are being sold, perhaps by the manufacturers, perhaps by the jobbers at the figures named.

The character @ is used to indicate a range of price; thus discount 50&10@50&10&5 % signifies that the goods in question are sold at prices ranging from discount 50 and 10 % to discount 50 and 10 and 5 %.

News and Notes.

Grasshoppers and crickets have made their appearance in such unprecedented numbers in Idaho as to seriously threaten the existence of the crops. Like the Egyptian locust they devour every green thing in their line of march.

A combined electric and inclined railway is nearing completion at Pasadena, Cal., which is to connect Pasadena and Los Angeles with the highest peak of the Sierra Madre range in that vicinity.

The adoption of rubber tires for road vehicles is being strongly urged in various quarters and the idea appears to be favorably received. A company in New York, who have started the manufacture of these wheels, report that they are overwhelmed with orders. Rubber-tired wheels have long been in use in European cities. They serve the double purpose of saving the conveyance from shocks and jars and of being practically noiseless in operation.

Montreal, Canada, is suffering from a blockade of hay, which is being sent down for shipment to England in greater quantities than can be conveniently handled at the wharves.

The Rapid Transit Commissioners in New York City have consented to grant the officers of the Manhattan Elevated Railroad until August 17 to decide whether they will accept the terms proffered to them in regard to immediate extension of facilities and increase of those upon existing lines. It is understood that the Manhattan corporation is unwilling to embark upon further large expenditures during the present financial stringency.

One day's cattle shipments through Denison, Texas, recently, over the Missouri, Kansas & Texas road, amounted to 368 carloads.

What is said to be the largest alternating current electric motor ever set up is being tested at the works of the Hartford Electric Light Company, at Hartford, Conn. It has 300 horsepower, and requires 3000 volts, reduced by transformers to 600 volts.

A glut of the worst kind obtains in the provision markets of the principal European countries, so far as American shipments are concerned. These are stated to have been unprecedented in volume to England, France and Germany during the past few weeks; and as hay and feed are so dear on the other side the imported cattle have been sold for anything they would fetch.

The "Paris" broke the westward record from Southampton on her voyage last week. The time of the American liner was 6 days, 9 hours and 37 minutes.

Agitation goes on in some quarters with the object of continuing the World's Fair for another year.

The Navy Department has formally accepted the cruiser "Detroit," built by the Columbian Iron Works of Baltimore, and has authorized the payment to the builders of reserved funds amounting to about $225,000.

The possibilities of wealth in the utilization of waste was never more strongly exemplified than in the case of cotton seed. Thirty years ago it was thrown away or used as a fertilizer. To-day an industry is based on the material of which the products are worth $27,000,000 a year and which is rapidly increasing. Cotton-seed oil and oil cake are recognized and valued commercial products.

A St. Louis journal figures out the world's wheat crop to be 100,000,000 bushels short of that of 1892.

Crops in the South are reported to be in fine condition, and the yield promises to be greater than that of last year. In 1892 the product was as follows:

Cotton	$332,000,178
Cereals	386,864,500
Tobacco	37,314,550
Sugar and molasses	29,898,650
Rice	10,212,462
Potatoes	17,420,800
Hay	23,647,500
Fruit	25,000,000
Other farm products	233,460,500
Total	$1,095,869,140

The report of the treasurer of the Calumet & Hecla Mining Company's Aid Fund, for the year ending May 1, 1893, has just been issued. It shows the amount of collections for the year to be $20,314.75; amount donated by the company to be $20,314.75; total, $40,629.50. Dividends and interest, $8325.55; unclaimed orders, &c., $90.32; total receipts for the year, $49,045.37; balance May 1, 1892, $23,161.66—$72,207.03. Payments, orders as per list, $31,783.82; 116 shares stock C. & H. Mining Company, $32,653; printing not paid by order, $6.25; cash on hand, $7763 96—$72,207.03. Summary of payments: Paid for sickness, $21,424.70; for accidents (three fatal) $1500; accidents, $8358.90; partial disability, $200; other amounts, $300.22. Statement of funds: Cash, $7763.96; 388 shares stock C. & H. Mining Company cost $91,459.32—$99,223.28.

The general report on the foreign commerce of the United States was published last week. The following table shows comparison of the official figures on merchandise traffic with those of last year and for the two preceding months:

Exports.

	1893	1892.
June	$65,416,367	$64,888,337
May	68,742,612	69,703,479
April	59,874,237	75,954,962

Imports.

	1893.	1892.
June	$75,832,084	$72,016,568
May	79,798,120	68,696,171
April	84,997,522	76,341,449

A Chicago dispatch reports that lake business showed a material improvement on all the principal lines of traffic, and the feeling in marine circles was that business was destined to steadily improve. It was thought that the bottom had been reached, and that there would now be a slightly better figure paid for water transportation, although no one was hopeful that the big promise of a highly profitable season of last spring was to be fulfilled. A Buffalo dispatch states that coal has begun to be shipped again, and that a part of the vessels tied up there waiting for cargoes have secured loads and are moving again. At Duluth, where the Buffalo wheat rate brought the unprecented figure of 1 cent a bushel to Buffalo, there was an advance to 1½ cents.

According to the report of the Secretary of the Treasury the export of corn and wheat from the principal shipping ports was as follows for the year ending June 30:

Corn.

	Bushels.
New York	12,296,243
Boston	3,596,836
Philadelphia	4,252,443
Baltimore	6,524,162
New Orleans	4,265,749

Wheat.

	Bushels.
New York	39,519,574
Boston	3,806,878
Philadelphia	9,424,410
Baltimore	14,218,961
New Orleans	14,290,360

The New York *Press* asserts that $345,000,000 of American capital has been invested in business enterprises in Mexico during the past three years.

Owing to change of printers, two issues of the *Patent Office Gazette* have failed to appear.

Sixty-seven new canning factories were established in the South during the first half of this year.

The index for *The Metal Worker*, Volume XXXIX, January-June, 1893, is now ready and may be obtained on application to David Williams, publisher, 96–102 Reade street, New York; or to 220 South Fourth street, Philadelphia; Room 509, Hamilton Building, Pittsburgh; 59 Dearborn street, Chicago; Rooms 22–24, Pickering Building, Cincinnati; Bank of Commerce Building, St. Louis; 146 Franklin street, Boston; 312 Cuyahoga Building, Cleveland.

Discouraging Outlook for Business.

The business situation steadily grows more unsatisfactory. Trade is shrinking in every direction, and all branches of business are participating in the distress which envelops the country like a dismal fog. The wail of the unemployed is heard on all sides. Factories are idle that had not been known to close except for repairs within the memory of the present generation. Towns that have never before felt the blighting touch of adversity are struggling with the problem of feeding the hungry, who almost outnumber the fortunate ones still blessed with employment. In a manufacturing city in the central West, possessing diversified industries in such an advanced state of development that its prosperity seemed founded on a rock-rooted basis, there is at present not a single establishment of any moment in operation, and a loaf of bread is not to be had on credit. The inhabitants have seen paralysis affect one industry after another, and they now understand for perhaps the first time in their experience what is meant by hard times. No relief is to be had by tramping to some other locality where there may be factories in operation, because those are probably running on half time or with a reduced force, and there is no chance for a stranger.

Solvent Bankrupts.

It seems like mockery in such a time as this to say that the country is really in a sound condition and that the distress is of an artificial character. But was there ever seen in the history of the world such a series of financial reverses among really solvent institutions? Manufacturers fail with assets largely in excess of their liabilities. Banks go to the wall with their safes filled with good securities. Merchants close their shutters because they are only in need of a comparatively small amount of cash to discharge pressing liabilities. In the throng of insolvents there are, of course, not a few who had attempted to carry too heavy a load for their capital, but this country can now show the most remarkable collection of solvent bankrupts ever seen under the canopy of heaven. Business men of all kinds have taken refuge in receiverships, that they may secure the protection of the courts in saving valuable properties that would be ruthlessly sacrificed in this crisis. There appears to be no value at present in any kind of property whatever, and to offer it for sale means to instantly depreciate it enormously.

Needs of the Currency.

The restoration of values appears to be a simple matter and to lie wholly with Congress. The early repeal of the Sherman act and the authorization of a bond issue to increase the gold reserve, thereby insuring the maintenance of our silver currency on a par with gold, would impart confidence to the people at once, and the further hoarding of money would be checked. It will, of course, require some time for trade to resume its wonted course, as the disturbance to business has been very great. There may also be some halting in certain branches of industry and commerce until it is definitely known what changes may be made in the tariff schedules. But the first thing necessary to check the awful demoralization in the business of the country is to re-establish our currency on a sound basis. To this end all patriots should earnestly work, and partisan cries should be stifled until it is accomplished.

The Blower System and the Tinsmith.

The introduction of the blower system of heating and ventilation has opened up a new field to the tin and galvanized iron worker. The extended systems of piping required for the air distribution by this method generally consist of pipes and ducts of such size as to make galvanized iron the best material for their construction. These pipes will vary from 5-inch to 6-inch for branches up to 50 inches and 60 inches for the mains, and in aggregate weight for a single apparatus will run from 2000 pounds for a small or medium plant up to 20,000 and 30,000 pounds for some of the largest. While the majority of this work is comparatively simple in character, yet considerable skill and experience is required in laying out and making transition and complicated outlet pieces. For the better class of installation, rectangular pipe is employed to a considerable extent, these ducts or flues running flush either between floor timbers or inside partition walls. In the application of the system to old buildings, such as manufactories, the complication of belting and shafting frequently throw upon the metal worker the responsibility of successfully putting in place the piping that the draftsman has only been able to roughly locate.

Home Application of Tight Money.

The young wage earner with steady employment naturally does not feel the much talked about money trouble and gives it little heed. A search for its existence, however, will be advisable as a matter of information that will be valuable. Though a thorough understanding of money in its broadest sense will not be gained from the first inquiries, the search will show that the wage earner, as an article of trade, is among the first to feel retrenchment in the business world. It will be learned that whenever the commercial outlook is not promising a cutting down of expense follows, and that a good portion of the saving is effected by paying out less for wages and by laying off some workmen. From a study of the past and a talk with old workmen it will be found that financial depression and its disagreeable attendants are experienced several times in a workman's life. Those who make no provision to pass through such times suffer many privations, and instead of profiting by their experience when employment is again found they far too often are embittered by their trials and continue improvident.

Live Within Your Income.

Continuing the same line of thought an excellent example is set by those who have accumulated one or two fortunes, yet are reducing their expenses so as to live well within their income, in order that their principal may remain untouched and they need not ask for credit, which is hard to get in hard times. The wage earner, to follow a similar course, would set aside each week one, two or three days' earnings for investment to provide for emergencies. Another worthy ambition would be to develop a skill in handicraft and acquire a knowledge of their trade that would insure employment in any condition of business. To live well at small cost is a problem

worthy of solution and should be studied until it becomes a simple matter. Examples are common of those who have solved this problem and have met expense in sickness, accident and lost time, and have lived well in every way, and yet, after a period of years, have a neat sum invested or have a home. In times like the present every earner of wages should study and profit by the experience of those who have safely weathered former periods of depression.

Wit and Lack of Wit.

The proportion of those who live by their wits in this country appears to be on the increase. In this class it is not intended to include gross criminals. As the country gets older, and competition in trade grows sharper, as the making of a good living by straightforward methods becomes more laborious, those who will seek to shirk the burdens imposed by increase of competition will naturally become larger. One needs to look only into the history of civilized countries and study statistics of fraud and of current criminal records to be convinced of two things: First, that, as to live honestly requires more stringent effort and greater self-sacrifice, the more will a certain class of men and women be diverted into crooked ways in the endeavor to evade their share of the world's honest work. So long as there seems a possibility of their maintaining themselves by fraudulent practices easier than by working the ranks of this class will be filled. Second, it will appear that there is another class that are also seeking to evade work, or at least seeking to make their lives easier by speculation, and become easy victims to the tricks of sharpers.

The Dupes.

Those who live by their wits would find it harder to provide for their wants and wishes in this manner than by honest work were it not for the lack of wit in others. It seems that schemes for obtaining money of witless people prosper in proportion to the inherent improbability of the statements and promises made to allure their victims. Reasonable assertions do not attract; it is the promise of enormous, impossible gains that draws these moths into the flame that burns off their wings. An offer of a dollar for every dime invested, loaded with the almost certain risk of total loss of the original investment, will oftener find takers among this the never failing army of the gullible than one of a profit of 10 cents on a dollar invested with reasonable assurance that the promise will be performed and with scarcely any risk of loss, even if the profit expected be not fully realized. What wonder, then, that the annual crop of simpletons should invite harvesters, since it appears an easy and profitable field for enterprising sharpers, and since this field extends through all classes of society, from highest to lowest?

Sanitation and the Churches.

The social work of the churches in laboring to advance the physical well-being of the masses in great cities is a feature which is coming more and more to the front. It is recognized that a great barrier to success in work among the poor and neglected is in their unclean and unwholesome environments, in the unattractive and unsanitary surroundings of the places where they dwell and work and sleep. To improve these conditions is a specific work that certain religious bodies and isolated workers in the interests of the churches have resolutely set out to do. A favorable instance of labor in this field is found on the other side of the water. The Church of England Sanitary Association is an organization which has for some time been steadily doing a praiseworthy work in the British Isles. Some of the most influential and practical of the clergy are enlisted in the ranks of the association, the object of which is the furtherance of every measure which shall improve the sanitary conditions of the homes of the poor in the various parishes in which the society is represented. Its labors in the East End slums of London in bringing to light and knowledge dangerous and unwholesome districts which have escaped the more perfunctory sanitary inspector's eye have been very fruitful. The association, which is made up of common-sensed, practical individuals, who know from experience better than almost any other class of men the miserable conditions under which the poorest live in the cities, numbers among its workers and counsellors some of the best-known sanitarians and scientific engineers of the country, who lend it hearty aid. By its means many useful measures for the improvement of the dwelling houses of the poor have been furthered and carried out. Personal influence is also brought to bear on those they seek to benefit. Cleanliness and sweetness, and subsequent morality and happiness, have been brought about in many quarters through the sanitary crusade of these sensible philanthropists.

Both Sides of the Counter.

BY F. S. L.

There has been considerable said and written regarding the amenities of the retail trade and much advice offered, chiefly to the inside of the counter, as to the proper and especially the profitable treatment of possible customers, which doubtless has resulted to the moral and financial advantage of those dealers who "live to please" because they must "please to live." Perhaps the outside of the counter may have been neglected too much in the distribution of trade pointers and this may warrant our acceptance of a mental call to sit judicially "on the counter" with words of wisdom (?) for the parties interested, but bearing in mind, as above stated, the proportion due to each. We have to accept the fact of an irrepressible conflict between buyer and seller which does not exactly accord with the teachings of the Golden Rule.

This manifests itself in a sort of diplomacy which is *lie*-able to deceive, but does not always show itself in oral prevarication and is likely to hide selfish motives behind words which at best are but half truths.

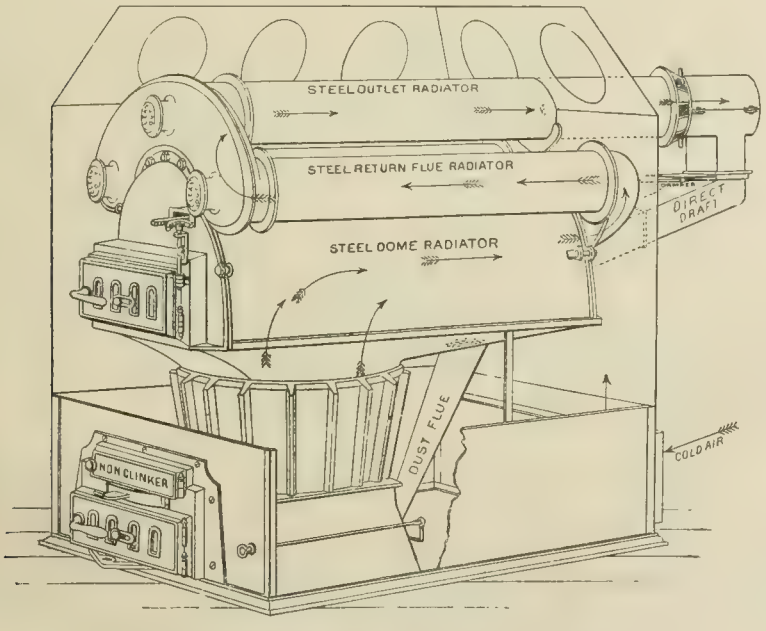
We may infer that Solomon the Wise was, by reason of his extensive feminine connection, quite familiar with outside-the-counter remarks, and his "It is nought, it is nought, saith the buyer, but when he is gone his way then he boasteth," was a record of experience which has been and is now common to all. Mrs. Solomon—in the plural—was an antitype of many of the present generation who will not purchase even a necessity without condemning the seller's goods in order to get a reduction in price. When Mr. and Mrs. Skin Flynte are obliged to put a new stove in place of the old inherited and played out one their minds are made up, or at least hers is, to get the "Cream of the Kitchen," because that is highly recommended by sundry sisters, cousins and aunts. In vain do Rostem & Co. talk of the merits of their wares. Mrs. F. will have none of them, and is firm in the belief that a seller of stoves knows less about them than a user. Having found the only place in their locality where the "C of K" may be procured, they (Mr. and Mrs. F.) immediately compare it unfavorably with "that one we saw at Rostem's" which was of the same price, but "better looking and a leetle bigger." Of course the stove is bought as was intended, and its merits extolled to visiting neighbors with the self-approbative remark that "I made him throw in a poker, and a rattlebox for the baby."

We think a little of "put yourself in his place" would be good for both sides of the counter; the buyer realizing that the fact of carrying a stock of goods for him to select from warrants a profit on their sale, and the dealer feeling that the same fact gives him a right to so-called patronage. As a rule, the inside of the counter is the most humble servant of the outside, and to be waited on implies a servile acquiescence in all the unwarranted demands often made upon the dealer's time, patience and temper. Sometimes the airs that patrons put on are resented, as in a case that comes to memory. It was in a country store where a general stock of assorted merchandise was kept. One day when trade was extra good a man asked the boy clerk to give him change for a $5 bill, to which the clerk objected, saying that the little in the cash drawer would be needed for customers. "What is the price of that?" said the man pointing to an article. It was immediately laid on the counter with the answer, "fifty cents." "I will take it," said the man, "and now" (with an oath) "you'll have to change the bill." "Hold on," said the proprietor, who had seen and heard the transaction, "we don't have to do anything of the kind under compulsion. The article is not for sale to you, and we won't change your bill." Of course that man's present and prospective patronage was lost but not regretted.

It has been said there are no friendships in trade, but it does not follow that there may not be mutual confidence, although as that is a plant of slow growth it will be a long time before it flourishes across the counter, replacing the prevailing distrust which makes small trades a skirmish and larger ones a campaign. Both parties may be free from direct deception, yet each will allow the other to make self-injuring mistakes, with the after comment that "I look out for myself and others must for themselves." A lady came to a dry-goods store with a sample of cloth she wished to match, which the clerk could do in color but not in quality, thus losing the sale. The boss said, in reprimanding the clerk, "Why did you show the best piece first?" "Because it was most like her sample." "Next time begin with the coarser goods and afterward show the finer and better, which will then appear more so to a customer." Will the reader please estimate the moral,—not mercantile—value of that advice.

The Miller-Monitor Steel Dome Return-Flue Furnace.

The Wm. Miller Range & Furnace Company, Cincinnati, Ohio, are making the furnace shown in the illustration. Consistent with the disposition to use larger quantities of air, to secure comfortable temperatures, the square or rectangular shape is said to have some advantages. From the illustration a good idea of the construction and operation may be gained. The fire pot presents a large heating surface by means of extending flanges. It is located near the front, on the ash pit, which is provided with a dust flue, which opens near the direct-draft passage. The grate is a patent of the draw center, anti-clinker style, with which a poker can be used if desired. The section above the fire pot presents several novel features intended to secure an absolutely gas proof furnace and to extract the greatest possible heat from the fuel consumed.



The Miller-Monitor Steel Dome Return-Flue Furnace.

The lower radiator, which sets in a secure joint on the top of the fire pot, is a heavy casting in one piece, designed in a special manner to receive the steel dome and its cast-iron heads.

The connections between these parts are made secure by the shape, the packing and the re-enforcements. Connecting with the rear dome head are two steel plate return-flue radiators, one on each side, connecting with a crescent flue head at the front, where they merge into an outlet radiator, which connects with the smoke pipe at the rear. The rear dome head has a direct draft outlet, which is connected with the feed door by a rod and a contrivance which opens the damper when the door is opened. The erection of the outside casing is very simple, and, being of galvanized iron lined with non-conducting material, but little heat is lost. At the rear is a large opening for the air supply, which is distributed through the furnace over the heated surface by means of properly located guide plates. The furnaces do not stand high, and good ascent is gained and ample opportunity for a large number of pipes afforded by the long flat sides and ends, to which hot-air collars may be attached.

Anthracite Coal Bricks.

The London *Times* contains a description of a new industry which may obtain a hold in England—an industry which is likely to benefit the community at large, and which will utilize a great amount of what has hitherto been considered waste material. This is the manufacture of what are called "briquettes," being small blocks of fuel made from coal dust, cemented by a special compound and prepared under great pressure. These are said to have not only a greater heating power, but also to give off a less quantity of smoke than usually results from the combustion of coal in the raw condition. They can be made either from anthracite or other coal; but the former is preferred on account of its smokeless character, especially as the bricks are particularly recommended as a cure for the smoke nuisance and London fogs. Owing to its non-bituminous nature, difficulty has been hitherto experienced in burning anthracite in London, except under special conditions, and this has proved a barrier to its more extended use. This difficulty now appears to be overcome, and the fuel is offered in a form in which it can be universally used. In this block fuel the grains of dust are made to adhere by a cementing compound which is the secret of the syndicate who are operating the invention. The manufacture of artificial fuel from coal dust is, of course, not new, pitch being used as a binding material. Pitch, however, carries with it the disadvantages of burning slowly and giving off offensive fumes. Other cementing substances which have been tried have all been placed in the category of failures or only partial successes. At length, however, a cementing material is said to have been discovered which is the very opposite of pitch, being a dry powder. This powder is composed of two natural substances, which are both cheap and abundant, and which, moreover, give out no noxious fumes during combustion and have no deleterious effect on the flues or plates of steam boilers.

MANUFACTURE OF COAL BRICKS.

The process of manufacture of these coal bricks as carried out at Robert Middleton's works, Sheepscar Foundry, Leeds, England, is described as simple and inexpensive. The coal dust is mixed with the binding material in the proportion of 96 per cent. of the former to 4 per cent. of the latter. The compound is fed into a mixer, where it meets a jet of steam, a stiff paste being formed, which is delivered successively into a series of molds under a pressure of 25 hundredweight. As the mold plate revolves the charge in each mold is brought between two rams, which exert a pressure of 2 tons per square inch on each side of the charge, forming a very dense and homogeneous coal brick. The brick, still in the mold, passes on to the delivery ram, by which it is pushed out on to a table and is removed for the market. These coal bricks are found to make an excellent fuel and to possess a very high efficiency for steam-raising purposes.

TEST FOR STEAM PURPOSES.

A practical test of the fuel has been made at the Atlas Steel Works of John Brown & Co., Sheffield, which appears to prove conclusively its value in this latter respect. The bricks were made from American anthracite coal, as used by the Inman Company on their eastward voyages, and the test was rendered comparative by using anthracite also in its natural condition, the same boiler being employed in both trials. According to Messrs. Brown's report, the total horse-power developed by the boiler with the natural anthracite was 368.1, while with the bricks it was 506.6. These figures are based upon the Admiralty rule of an evaporation of 20 pounds of water per hour being equal to 1 indicated horse-power. The importance of this result will be seen by practical men, while shipowners will recognize the value of a fuel which can be stowed conveniently away in square blocks. So highly do Messrs. Brown & Co. appreciate the invention that they conclude their report by expressing the opinion that, if very small American coal dust could not be obtained at a reduced price, it would pay the large steamship companies to have the natural coal ground small and made into bricks. The manufacture of these bricks is, of course, not restricted to anthracite, as the ordinary coal dust, of which many thousand tons are lying waste at collieries, can be similarly utilized, as also can coke. With such a fuel as that under notice, says the *Times*, there is room to hope for a reduction in the pollution of the atmosphere of towns as well as a reduction in the coal bills of our steamship companies and of steam users generally. The invention is being worked by the Coal Brick Syndicate of 2 Trafalgar Building, Northumberland avenue, London.

There are no trades unions in India. The workmen are, however, said to have in many instances a common understanding, an unnamed and unwritten bond of union, peculiar to themselves, by which the labor remuneration in various trades is generally regulated. No strikes or lockouts of general importance have occurred in India, and nothing in the nature of disputes involving organized action on a large scale between labor and capital.

The Irish "bull" is still rampant. A Dublin paper recently explained why there was not more cheering for the royal bride and bridegroom at the recent wedding in London by saying that the hot weather chilled the enthusiasm.

THE LETTER BOX.

How to Line a Tank.

From B. H. T., *Wisconsin.*—Having a tank to line I apply to the Letter Box for information. The tank is made of wood and is 4 feet square and 8 feet high. I have never done any work of this kind, though I am a tinner and have done all kinds of work at the bench for 15 years. Shall I use copper or lead, and how heavy? If lead is used, how must it be supported to prevent bulging and sagging. If I use copper, will a good lapped and soldered seam answer, or should it be flat seamed, as in roofing.

Note.—It is inferred from the letter that expert work can be done with a soldering copper, while tools for either lead burning or seam wiping could not be manipulated; consequently, though the first cost is greater, it will be better to use sheet copper that is tinned on one side and weighing 16 ounces to the square foot. Owing to the difficulty in soldering upright seams they will be avoided by commencing to line the tank at the top. Put together enough sheets of copper to make a piece that will cover all four of the inner sides of the tank neatly after the ends have been seamed and soldered securely, making a big cylinder. Before the last seam of the cylinder is made turn a flange an inch wide out at the top to be nailed to the wood and a narrow edge in at the bottom to receive a similar edge on the top of the next sheet to make a seam that can be easily soaked with solder. Both the flange and the edge should be notched at several places to permit the cylinder to be folded for handling to get it into the tank, or else they may both be turned after it is in the tank. When the cylinder is in the tank it can be fitted into the corners by driving a piece of square hard wood against the metal at the corners. After it is fitted and nailed at the top see that the edge turned at the bottom is in good condition and put in the next cylinder, getting the top edge over the edge on the sheet that is in place, then flatten the seam carefully with a mallet and proceed till the bottom cylinder is reached. On the lower edge of the bottom cylinder turn a flange in 1 inch and be sure that this flange rests on the bottom of the tank. On this flange turn a narrow edge, to which the bottom is to be seamed. Putting in the bottom is a simple matter. Now solder all the seams, thoroughly soaking them, and, as there are no upright seams, this will not be a difficult job. No nailing is necessary, except around the top of the tank, unless a few nails are used here and there for convenience. If the tank was so situated, and of such a size that it could be readily turned on its side, the job would be comparatively simple. If lead is used it should weigh not less than 4 pounds to the square foot and have a lap of at least ¼ inch if it is to be soldered with a copper. It is nailed to the wood with small-headed tinned nails 1 inch long 2 or 3 inches apart. For ¼ inch each side of the lap the lead should be scraped bright to take the solder freely, whether from a copper or wiped on. Lead comes in such widths that a seam around the bottom and one in each corner would be all that would be needed in a tank of the dimensions given. To prevent sagging or bulging sometimes several nails or screws are put inside of a small circle and a piece of lead soldered over them, which is called a "bull's-eye." Nails 15 or 18 inches apart, with their heads securely soldered over, will hold the lead in place. It is impracticable to attempt to properly solder with a copper an upright seam in sheet lead, and it is very difficult to solder cross seams. Even if the tank could be turned to permit soldering the lead would tend to drop away from one side while soldering the other. Consequently, if a plumber cannot be secured to wipe the seams it will be better to use copper.

A Water Back Question.

From G. W. J., *Farmington, Ill.*—In answer to "W. F. S.," Bayfield, Wis., whose letter appeared in *The Metal Worker* of July 8, I would advise him never to try to use a coil water back or cast water back. Instead, let him use a coil water front made in the following manner: Run three pipes in front with close bends. Then at the opposite ends of the fire box from the boiler run pipe across the end fire box to center of long T center. Then turn to boiler, letting the pipe hug to T center, to give the draft over the oven plate all the space possible between the pipe and plate. Also give gradual rise to all coil pipes. Three-quarter inch pipe is large enough for a 30-gallon boiler, though the size of the pipe depends upon how much room there is between the oven plate and T center. Good judgment is all that is required.

Warming a Church.

From W. B. & Co., *Bangor, Maine.*—We notice in *The Metal Worker* of May 20 a plan of setting a church furnace. It does not seem right to educate the young men of the nineteenth century to set a furnace in a church so that a great part of the heat shall be wasted before it can pass into the church. We give the description of a method which we think practical furnacemen will concede takes at once all of the heat in the church. Place a 36 x 36 hot-air grate in the middle aisle of the church a little more than one-third of the way from the entrance and place the furnace directly under it and connect with a 30 inch pipe. The air then passes into the church and is distributed much better than it can be by four pipes. Exhaust registers, 16 x 20 inches, should be placed at each end of the church about equally distant between the middle and west aisles. We have, in the last 40 years, taken hot-air pipes out of a great many churches in this cold climate and have never failed to warm them satisfactorily when the furnace is set under a hot-air grate suitable to pass all of the heat into the church. Registers should never be used in a church, for if all are closed there is considerable danger of fire, and hot-air grates avoid any such contingency while presenting less resistance to the air current.

Calking Soil-Pipe Joints.

From D. B., *Passaic, N. J.*—Will you kindly give one of your old subscribers information on the following qustion: How much metal is required to calk the joints in 2, 3, 4, 5 and 6 inch soil pipe, both light and heavy?

Answer.—Lead is generally used for calking the joints in soil pipe and the table below gives the average weight of the lead used and the depth of lead packed in the joint, as reported by a number of practical plumbers:

Light Pipe.

	2-in.	3-in.	4-in.	5-in.	6-in.
Weight, pounds....	½	1	2	2½	3
Depth, inches... ..	1	1	1½	1½	1½

Heavy Pipe.

	2-in.	3-in.	4-in.	5-in.	6-in.
Weight, pounds....	¾	1½	2½	3	3½
Depth, inches.....	1	1	1½	1½	1½

It is generally conceded that the oakum packing under the lead should be done carefully and that it cannot be rammed too tight. The oakum packing should be ½ inch thick all round and driven down until it is as hard as lead. To do this properly the calking iron should nearly fill the space in the hub and be very heavy above, so it will not spring, particularly if it has an offset, and this applies to the irons for the lead as well. In pouring the lead in the joint some plumbers pour it full the first time and then calk once for all. A claim is made that a better way is to pour ½ inch of lead in the joint, and, with a full-size iron, drive in down hard; then use red-hot lead to fill the joint, letting the lead swell up above the bell as much as it will and then calk it down tight and flush.

Paste for Asbestos Paper.

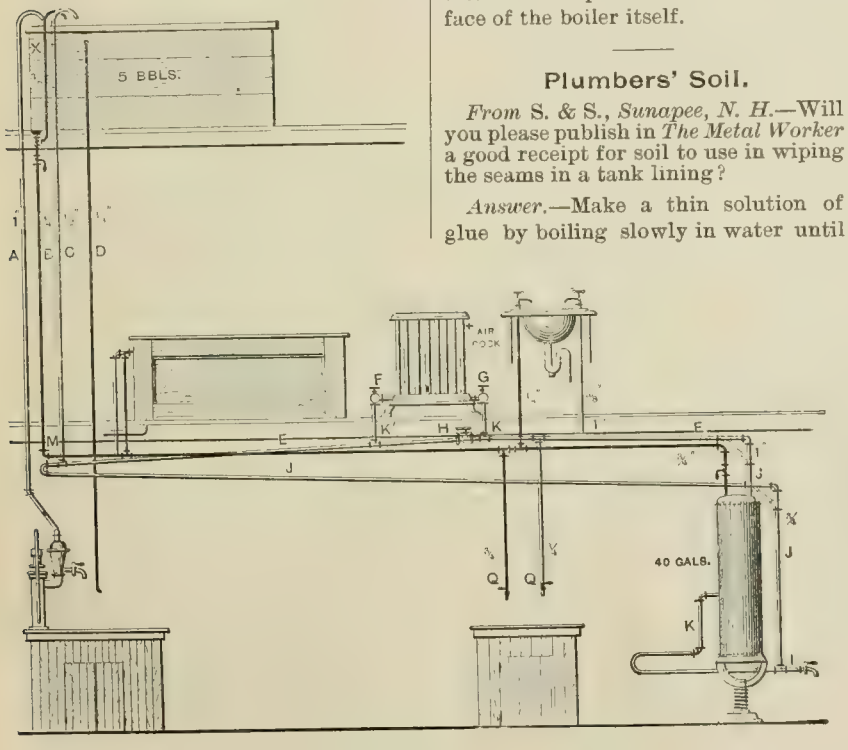
From M. J. H., *Williamsville, N. Y.*—Can *The Metal Worker* or some of its readers inform me what kind of paste is used for applying asbestos paper to furnace pipe? I have used flour paste, but mice destroy the paper and the fastening to get the flour.

Note.—Some furnacemen use Portland cement, as it sets quickly, and they roughen the surface of the paper before applying. Silicate of soda is used by some, mixed with Portland

cement. It is quite probable that this problem has been solved by some of our readers who can give a receipt which will avoid the labor of wiring and give the covering a neater appearance.

Heating Bathroom From Range Boiler.

From J. I., *New York.*—I send you herewith plan of a job I have to do, and wish to know if I can heat a bathroom 5 x 12 feet with radiator connected with the range boiler, as shown on the plan. You will notice that E is a 1-inch circulating pipe, being run beyond the radiator as far as the return bend M, the return J from there to boiler being ¾ inch. I propose to open F and G and close H to heat the bathroom, and reverse this to keep the bathroom cool in summer. C is a



Heating Bathroom from Range Boiler.

½-inch expansion pipe from the circulating pipe E, D a ⅜-inch telltale pipe, A 1-inch supply pipe from pump to tank and N circulating pipe to water front.

Answer.—To heat the bathroom specified our correspondent will need about 12 square feet of radiator surface. A water back or water front can usually be relied upon to carry about 50 to 60 per cent. more radiator surface than the surface of the boiler adapted to use with it. The exact relation of the heating surface of a front or back to the amount of radiating surface it will carry has not been determined, so far as we are aware. To carry with efficiency an amount of radiator surface of 50 per cent. more than the surface of the boiler itself the boiler must be covered with felt or some other non-conducting material, as, otherwise, much of the heat from the water will be imparted to the air and other objects in the room in which the boiler is placed. The plan, as shown by our correspondent, has been well schemed out, as a whole and will probably work nicely if he uses an open return bend at M, and instead of the right-angled elbows at the tops of the pipes J and J′ uses 45° elbows and gets easy turns of the current in the pipes at these points. He should endeavor to get an easy upward inclination of the supply pipe from the top of the pipe J′ to the tee marked K, and a corresponding downward pitch from the tee K′ to the return bend at M. The inch supply pipe should be large enough for a radiator of the size named if unnecessary obstructions are not introduced. Of course, if the amount of surface proposed be used for heating the bathroom the amount of hot water that the boiler can supply for other uses will be materially less than it could furnish were the only means of escape for heat to be the surface of the boiler itself.

Plumbers' Soil.

From S. & S., *Sunapee, N. H.*—Will you please publish in *The Metal Worker* a good receipt for soil to use in wiping the seams in a tank lining?

Answer.—Make a thin solution of glue by boiling slowly in water until entirely dissolved. Then stir in lampblack sufficient to make the mixture of the consistency of paint, simmering the compound over a slow fire for 15 minutes. To test it, paint a space on a piece of pipe and rub it briskly with a dry finger; if it rubs off easily add a little glue, but if it sticks and takes a slight polish it is good.

Loss of Water From Boiler.

From J. & R., *New York.*—We have had a very curious experience with some hot-water heaters, and would be glad if any of the readers of *The Metal Worker* can assist us with an explanation. We want to know where all the water goes to in hot-water heating. We have put in two different heating plants, using different boilers in each case, but the house owners were compelled to be continually pouring in water. Sometimes the entire plant had to be refilled. It was impossible to find any leak or waste, and we are consequently very much puzzled to know where the water went to.

Note.—We presume from our correspondents' complaint that the refilling was frequent and the waste could not therefore be accounted for merely by the evaporation in the expansion tank. Many apparent inexplicable questions have been cleared up by our readers, and if they can assist in this instance we will be glad to hear from them.

Problem in Hot-Water Fitting.

From F. V. S., *Lancaster.*—Can you tell me whether the system shown by the inclosed drawing is practical? I have a number of water jobs and would like to use it, having seen it set up where it seemed to work well, but having learned a great deal from *The Metal Worker* would like to know its opinion of this case.

Answer.—The drawing shows a boiler with flow and return pipes running around a cellar, and at one point two Y-fittings are so placed that the hot water easily flows through one into a pipe to a radiator on a floor above, and the return from the radiator enters the main return through the other Y with little friction, and the system should work freely. The drawing is defective and may be intended to show the boiler and radiator on the same level, in which case there is an uncertainty of its working properly.

Trouble With Hot-Water Circulation

From S. B. R., *Haverhill, Mass.*—Please inform me why the hot water does not circulate in the following job: The bottom of the boiler is 18 inches below the water back. The hot-water return pipe has a slight sag between the water back and boiler. The hot-water supply from the top of boiler first runs down to the cellar, then along the floor timbers and then up-stairs again. A branch pipe is taken from the pipe down-stairs to basement sink. I know that a sag in a pipe will cause thumping in a boiler, but will it stop the circulation? If not wholly, to what extent? As a remedy to make the water circulate I propose to raise the boiler somewhat and straighten out the sag in the pipes, and also change the piping so that the hot water supply pipe runs up-stairs first and then return it to the basement sink. There has been some difference of opinion as to whether or not my plan is correct.

Answer.—A careful reading of the letter of our correspondent leaves little doubt as to the cause of the trouble. As to the changes suggested, we fully agree with our correspondent, although it may not be imperative that the boiler be raised if the cold-water supply has adequate pressure. A slight sag in the return pipe will not entirely stop the circulation, but it tends to impede it more than is generally appreciated. The proposed change of the hot-water pipe from the boiler, leading it up-stairs first and then down to the basement, is correct.

Tobacco Drying Apparatus.

From T. A. S., *Tennessee.*—Will the readers of *The Metal Worker* help me out with information on an apparatus for drying tobacco in barns? We are beginning to have calls for something for that purpose in this section and do not know what is being used. If there is some special heater in the market that requires to be put up in a special way we would like to hear about it.

Interpreting a Roofing Contract.

From O. & K., *Ohio.*—We would like to have your opinion and the opinions of some of your subscribers in regard to laying a tile roof. The following is a copy of the specifications: "Cover all roofs with first quality shingle tile, laid with proper lap Wherever necessary it must be pointed up with cement mortar the same color as the tile and to be made water tight. The tile to be underlaid with a course of heavy roofing felt, to be storm proof of itself. The tile laid in cement where necessary." The manufacturers sell no more than 2 inches to the lap and say that is the proper lap, and that the words "cement wherever necessary" means up a valley, around a skylight, scuttle hole or chimney and all such places where tile have to be cut in order to make them fit. The architect seems to think he has the right to interpret the specification to mean that the roof must have 3-inch lap and be laid in one solid body of cement.

Note.—The decision of the question presented depends upon two questions of fact, namely, whether it was necessary that the roof should have a 3-inch lap or a 2-inch or less lap, and whether the words "cement wherever necessary" mean a solid body of cement or only cement in certain places, such as around a skylight, &c.

The contract calls for a "proper lap," and the use of the word "proper" in a building contract has always caused great uncertainty and dispute, and frequently litigation. The legal principle which can be deduced from all the decisions of the courts on this subject seems to be that the work must be done in accordance with the usual best custom. As applied to this case, there must be no careless, or possibly imperfect, work; there must be no undue economy of material; and if it is the custom to lay the tile with a 3-inch lap in the same kind of houses, that custom must be followed. What the manufacturer of the tile says about 2 inches being sufficient is, of course, important, and it is the strongest kind of evidence that 2 inches is the proper lap, if they all, or many of them, manufacture their goods on that basis. At the same time their decision or opinion is not final. If it can be shown by the architect that for any good reason a 2-inch lap is not proper in the particular case, and if that could be made to appear to the satisfaction of a number of men, such as a jury, for instance, then the terms of the contract call for the 3-inch lap. The ultimate and final appeal in questions of this kind is, of course, to a court, and the question in each particular case can only be settled by a verdict. "O. & K." fail to state any reason advanced by the architect for his opinion, although it would seem that the architect must have some reason, more or less plausible. With only one side of the case before us, therefore, it is impossible to venture any definite opinion as to the merits of the question.

The question as to the cement depends for its answer very largely on the same principles. Who is to be the judge of what kind and amount of cement is necessary? It would hardly seem reasonable to insist that the whole roof should be laid in one solid body of cement, and yet such might be the case in any particular instance. The fact, however, that the language used in the contract merely calls for cement "wherever necessary" would seem to imply that in this case it was clearly considered that there would be places where it would not be necessary. The intention in the minds of the parties to the contract was very likely what "O. & K." state—namely, that the cement work should be confined to places such as chimneys and skylights. If it could be shown that it is unusual to lay the roof in one solid body of cement, these two facts taken together are practically convincing, as against the contention or claim of the architect. Some contracts provide that the architect shall have power to decide what is "proper" and "necessary." Some contracts give architects almost unlimited power as to the construction of the specifications, and if both parties have agreed to abide by his decision there is, as a rule, nothing to do except to comply. If such a clause is embodied in this contract it would clearly affect the question very materially.

Altering Roofing Contracts.

From G W., *Lockhaven, Pa.*—I would like your opinion on the following: I agreed to put on a roof of Best Bloom galvanized iron at a certain price. The roof was to be plain standing seam, without hips or valleys. When I came to lay it, however, it was partly plain, but the main roof had four hips and six valleys, and the question is, Can I make the owner pay for the extra labor on that part? My contract was only verbal, and he has paid me part on it. The job is not yet completed, and I have not yet said anything to him about it. I would like your opinion and the opinion of some of your readers in this matter.

Answer.—It seems to us that it was the duty of "G. W." to notify the other party to the contract that the roof was different from that described and called for by the contract, and therefore that the price would be higher. "G. W." was employed to make a certain roof at a certain price. He was not employed to lay a different kind of roof at any other or higher price. In other words, he had no contract to put on the roof he did. The fact that the structure of the building necessitated a more expensive roof gave him no right to go ahead without notice. The course a prudent business man would usually adopt would be to inform the other party that he could not proceed with the contract at the price fixed upon, and also inform him what the increased price would be, stating at the same time the reason why the work would cost more. The other party could then decide whether he would have the work done or not. In case considered, if he determined not to give "G. W." the contract, the latter could nevertheless hold him for any damage or loss of profit which he might have sustained. This is the plain law of the case. Of course, as a matter of fairness, the other party, who has been benefited by the extra work, ought not to refuse to pay a reasonably extra sum, but it is open to question if he could be compelled to do so.

Hot-Air Heating.

From G. P., *Victoria, B. C.*—I take the liberty of sending you a cutting from the Victoria *Daily Colonist*, respecting certain heating contracts that have been given out. In it you will notice the following sentence: "2. Many eminent hygienic authorities condemn the use of hot air absolutely for schools, asylums and hospitals." What I want to know is, suppose that certain particular systems are failures, does it follow that all hot-air heating, according to the architect's idea, is also a failure?

Note.—To condemn hot-air heating in the broad way mentioned in the clipping sent us by our correspondent, is, we think, going beyond all reason. There have been many instances of failures in hot-air heating, and there have also been many instances of failures by steam and hot-water heating. The three systems are alike in one essential particular, they transfer the heat from the coal, or whatever fuel is used, to the air of the house. It may be done by a radiator over a hot-air furnace, by indirect stacks in the cellar of houses heated by steam or hot water or by radiators in the apartments of the building. In the latter case there is a certain amount of warmth due to the direct radiation from the radiator. Leaving that out, however, the heat is due to the higher temperature of the air. It makes no difference how the temperature is imparted to the air, provided a few ordinary rules are observed. If the furnace be so constructed that gas enters into the hot-air chamber, the air coming through the registers will be, to a greater or less extent, injurious. If the furnace radiator is heated to such a high temperature as to burn the dust particles in the air there will be an offensive odor. The question of moisture must also be considered; but that is a matter that also needs consideration in the case of heating by other methods. We think our correspondent, therefore, need pay little attention to this broad condemnation of hot-air furnace heating. The system has its defects, undoubtedly, but so has every other system of heating.

Barker's Chimney Top.

From D. O. N., *Chicago, Ill.*—In answer to the query where Barker's chimney top can be obtained, would say that it is manufactured by Barker Brothers, Braidwood, Ill.

Gasoline Burner Wanted.

From L. & J. A. Steward, *East Clarendon, Vt.*—We desire the address of a manufacturer of a gasoline burner suitable for heating a soldering pan 4 inches wide and 5 feet long, all to be done from one generator.

Gasoline Burner for Hot-Water Boiler.

From H. S. & D., *Charleston, W. Va.*—In reply to the inquiry of "R. L. S.," in *The Metal Worker* of July 29, we suggest that he put in a gasoline gas machine, and we advise him to correspond with Clarence M. Kemp, Baltimore, Md., who can probably give him some valuable advice in this matter.

In *The Metal Worker* of July 29, page 45, is a letter inquiring about flat seam roofing, from William Surrell. His address, however, should be New Madrid, Mo.

WORLD'S FAIR NOTES

Chapman Valve Mfg. Company

of Boston, whose works are at Indian Orchard (Springfield), Mass., make an exhibit in a conspicuous position on the central aisle of Machinery Hall. They have built an arched entrance composed of two brass pipes for columns which support a curved sign giving the location of the works and branch offices in the leading cities of this country and in London, England. These pipes are fitted with collars at short distances from one another, to which are attached valves, gates and cocks, in brass and nickel, beginning with very large sizes at the bottom and tapering to small ones at the top. At one side of the space are three large iron pipes supporting several tiers of straight-way water and steam valves, illustrating the variety of such devices manufactured by this company. In the rear is a fine walnut showcase containing highly polished brass valves arranged in tiers on two polished walnut pedestals. On one side of this case stands a column composed of gate valves resting on their sides, tapering from a very large one at the bottom to a very small one at the top. A similar column stands on the other side of the case, with the valves fitted with wheels. Fire hydrants are also shown.

One noticeable feature of this display is that the valves shown are taken from regular stock and not highly finished for the occasion, so that the visitor gets a correct idea of the quality of material and workmanship put into their goods by this well-known company. In all the power plants recently erected the tendency has been to increase the pressure of steam carried, so this firm call the attention of engineers to their complete display of valves and flanges especially designed for this class of work, and which have so fully met the severe demands made upon them. Among the special features shown, as applied to the Chapman high-pressure steam valves, with renewable bronze seats, are the outside screw and yoke, the by-pass arrangement, the ribbing of the body that it may not be affected by the expansion of the pipe line, and the self-packing feature on the spindle, by means of which the valve may be packed when wide open and the steam on the line. Both tongued and grooved and plain flanges are shown for high steam work, and may be used either bolted to valve or as flange unions. These valves may be seen in actual service as throttle valves in the Allis quadruple expansion engine, in Machinery Hall, as boiler stop valves on the Heine boilers, in the boiler house annex and at the power house of the intramural electric railroad, which has high and low pressure valves throughout, manufactured by the Chapman Valve Mfg. Company. The company make valves from ¼ inch to 48 inches in size, but only exhibit as high as 24 inches, as they are limited in space in Machinery Hall. In addition to the above mentioned are shown a complete line of brass and iron valves for feed and circulating systems and exhaust and low-pressure steam ; also ammonia valves for mechanical refrigeration and valve and fire hydrants for use on water mains. The display is so arranged that each valve may be easily examined and shows all varieties of end connection, methods of opening, indicating devices, &c., in a most attractive and appropriate manner. Edward L. Ross, M. E., is in charge of the exhibit.

Davies Bros. & Co., Limited,

Crown Works, Wolverhampton, England, make an exhibit of galvanized iron in the British section of Machinery Hall, under charge of J. Bayliss, their American representative. A number of specimens of plain and corrugated sheets are shown ; also pipes, elbows, crestings, &c. The Davies automatic galvanizing machine, owned and used by this firm, has just been introduced into the Whitaker Iron Company's works at Wheeling, where it has proved so satisfactory that the company propose to put in a second plant at their earliest possible convenience. The Cambridge Iron & Steel Company of Cambridge, Ohio, have also put in a Davies automatic machine, which is just getting to work in connection with a Wais & Roos leveling machine, made by the Wais & Roos Punch and Shear Company of Cincinnati. Mr. Bayliss is also negotiating with other galvanized iron manufacturers who are favorably impressed with the machine and expect to introduce it shortly.

The Niagara Stamping & Tool Company

of Buffalo, N. Y. (Section 28, Column L-46), make a very extensive display of tools and machinery for stamping, forming and cutting sheet metals. The exhibit includes almost the entire line of manufactures embraced in their revised catalogue of the current year, and is, therefore, a very complete exponent of the product of the establishment. The goods are all selected from the regular stock, and thus fairly represent their ordinary commercial quality. Amongthe larger machines may be mentioned several sizes and styles of punching presses, drawing presses, drop presses, squaring shears, bar and rod shears, and rotary, slitting and circular shears. Smaller sizes of the same class of machines are arranged for foot and hand power. All kinds of hand tools and small machines used for the various processes of manufacture of tinware and sheet-metal goods of every description are here represented and present a somewhat bewildering array, for their name is legion.

Iron Clad Mfg. Company

of New York make an exhibit of a unique character, entirely original for this occasion. They have a large square space, inclosed by a heavy nickel-plated railing. Above this is a frame work, with columns made of Milk Cans for bases, supporting ironclad, cold-weld Boilers, on top of which are small Milk Cans, surmounted by still smaller city delivery cans. These columns are connected by cross pieces, on which are hung small wares, such as Tea and Coffee Pots, Drinking Cups, Dippers, Spoons and Kitchen Utensils generally. Pipes also run from the columns to a central vertical pipe, 28 feet high, and are used to support cross bars, from all of which hang numerous specimens of the company's kitchen utensils, enameled in various colors. From the top of the central pipe hang wires, to which are fastened metal letters forming the name of the company. There are three entrances, over each of which springs an ornamental archway, with the word "Ironclad" in white enameled letters in the center. The Milk Cans supporting the columns are of different patterns, illustrating the styles in use in several cities. The Boilers are of a new and exclusive pattern, recently put on the market by the company. They are not riveted, but are welded cold, even the heads being put on without rivets. These are tested to 500 pounds, and are guaranteed to stand any water pressure in America. Inside the inclosed space are a number of tables, on which are a great variety of specimens of the company's enameled goods, while on the floor stand many patterns of Milk Cans. The whole of one side of the inclosure is covered with large plate glass mirrors, in a fine cherry frame, with the company's name overhead in white enameled letters. This exhibit is of such a distinctive character that it attracts unusual attention. It is located in the Manufactures Building.

Prize Competitions.

THE COMMITTEE to whom the contributions in Prize Competition No. 21 were referred have awarded the prizes as follows:

First prize to H. L. Chaffee.
Second prize to John C. Perry.
Third prize to W. N. Stevens.

Ventilation of the Mersey Tunnel, Liverpool.

An English correspondent of the New York *Sun* thus describes the method of securing ventilation in the railway tunnel under the Mersey : In the important matter of ventilation, the method resorted to in the tunnel beneath the Mersey at Liverpool is claimed to present one of the most striking achievements. Extending as does this tunnel deep below the bed of the Mersey to the solid red sandstone, and approached at either end by elevators of 70 and 90 feet lift, it was foreseen that ventilation was a necessity of the gravest character. The tunnel is large enough to avoid the piston action, its cross section being several times that of the trains, and at and near the middle of the tunnel are openings to a smaller side drift or tunnel running alongside of the main tunnel to the shore end, where is fixed a large fan, the result being that air constantly enters at the stations, which are thus swept clear of all foul air. A train starting in pure air at the station follows the air traveling in the tunnel up to the center, and any change of air between train and tunnel is thus less than it would be if the air in the tunnel were not moving. Past the tunnel center the train begins to travel against the moving air, by which time the air in the train will be more or less fouled by the passengers, and the ventilation due to train motion then begins to increase. The first air entering from the tunnel to the train is, perhaps, as good at that time as the air in the train, and, as the train proceeds, it meets purer air at every foot forward, and when it reaches the station is in air of surface quality again.

Most of us live and work and sleep, says an English exchange, in stuffy, fusty, badly ventilated rooms, which is one of the chief causes of all the illness that exists and of all the deaths that take place. Especially in the houses of the artisan class, the space allowed for each person is often less than a quarter of what is needed for health ; and it is important to remember that, whatever the size of the room, there should be an opening for fresh air to get in and another for foul air to get out, both of which should be as large as a brick (24 square inches) for every person in the room.

PLUMBING and GAS FITTING.

Master Plumbers of Newark, N. J.

In response to the call sent by the Committee of Five to the plumbers of Newark, N. J., and vicinity, 50 attended the meeting held at 86 William street on July 27, which was in every way satisfactory. A permanent organization was formed and the following officers elected: Elias Berla, president; C. E. Bond, vice-president; Jos. A. Smith, treasurer; Alexander Don, secretary; W. E. Mitchell, financial secretary, and an Executive Committee of five, as follows: Wm. Demars, Theodore Geiser, G. M. Crowley, C. Sullivan and J. Maguire, with the officers working with them as members of the committee. A committee was appointed to frame suitable by-laws, and after some explanatory remarks by different members the meeting adjourned for one week. A feature of the meeting was the enrollment of every plumber in attendance as a member.

Employer and Employed.

A member of the trade residing in one of the prominent cities of the "Nutmeg" State discusses the subject of employer and workmen in a manner likely to interest many of our readers. Among other things he says:

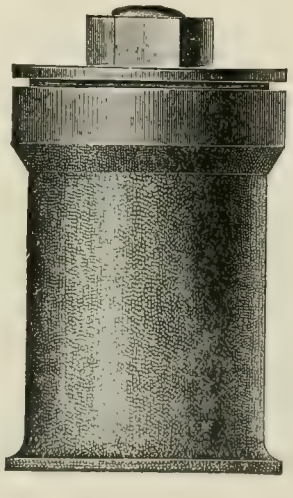
All men are created free and equal as to their rights to enjoy life, liberty and the pursuit of happiness. One may have money and no practical knowledge, while another may possess the knowledge and have no money. In the case of one who has money and no skill, it is necessary for him to employ a skilled workman to act as foreman, or head man, and see that the work is properly done. Here is where a great mistake often occurs. The foreman is a sort of go-between, with the boss on one side and the workmen on the other. Now, in order to have a good effect, a bond of sympathy should exist between the boss, the foreman and the men. Their welfare should be studied. A boss who is friendly to his men and gives them a kind word will generally find his men interested in his work, and that a kind word is better than a curse.

Permit me to say a word in regard to labor unions. A great ghost has risen and will not be downed. A union conducted as it should be will give the employer good men, as none but workmen should be admitted, and a union card should be a good credential for a job. A man working for another should be interested in the work as much as if he were a partner, for in one sense he is. If the boss has plenty of work he is busy and his influence with the customer will secure him work when others will not secure it. He should never be a time killer, or an eye servant, as he little knows who is watching him in these days of stock corporations. I would say work with might and main and there will always be work, for if you are known as a good and steady workman you can always secure employment.

The boss need never be too friendly with his men, but with a dignified and courteous kindness he can command the respect of all. In case of sickness or trouble a visit from the employer will be more appreciated than that of any other friend. A kind word goes a long way in the time of trouble. Too many men are watching the clock, wishing for quitting time, while others care nothing about wasting materials, stock and tools, and this waste will, in the end, make a large hole in the profits. Order is the first law of Nature. A shop should be kept clean and should be run with the motto, "A place for everything and everything in its place." In this connection it may be suggestive to remark, watch the dumping grounds in cities and see the number of people who live by the waste of others. In closing I would say to the boss, be kind and have a good word for all. The foreman should command the confidence of the boss and the respect of the men, and do all he can to improve the boys who are learning the trade. To the men I would say, be faithful and on time in the morning. Obey all orders from those above you, save stock and tools, and never for once think that the boss cannot get along without you.

Garvie's Clean-Out Ferrule.

Peck Bros. & Co., New Haven, Conn., and 47 Cliff street, New York, are manufacturing a clean-out ferrule, as here illustrated in Figs. 1 and 2, which is designed to be thoroughly proof against sewer gases. It is substantially made of cast brass, with a flange at the bottom. It is intended for use in soil pipes, and can be supplied in 2 and 4 inch sizes. Fig. 1 shows the fixture complete with cap partially screwed



Garvie's Clean-Out Ferrule.—Fig. 1.—General View of Ferrule.

down. Fig. 2 is a sectional view showing the method of construction. A brass cap or plug fits into a ground seat in the body of the ferrule, while the screw cap forces the two into close contact, thereby forming an air-tight seal against sewer gases. Once properly placed in position by a plumber the cap can be removed at will by any one and as easily replaced. This ferrule can also be furnished with a projecting flange on top to cover holes in finished floors or in places where the

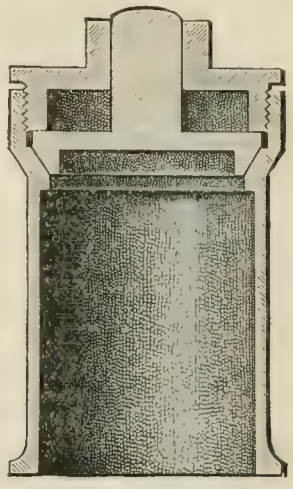


Fig. 2.—Sectional View of Clean-Out Ferrule.

top of the clean-out will be exposed. In such cases a nickel-plated top is sent if desired.

Plumbing Regulations in Yonkers.

The march of improvement in sanitation in New York State seems to have fairly set in, and defective plumbing work will soon be numbered among the "lost arts," under the influence of last year's legislation.

The city of Yonkers, which claimed to have had a good plumbing code, has been amending same under the authority of Chapter 602, Laws of 1892; and what has been of a more or less uncertain character has been definitely settled to the satisfaction of the health authorities and the plumbers. The Examining and Supervising Board of Plumbers and Plumbing, formed under the act aforesaid, and which is thus designated in cities other than New York, Brooklyn and Albany, is composed as follows:

Dr. Valentine Brown, health officer, chairman,
Robert Harper, master plumber, appointed for three years,
J. A. Lamont, journeyman plumber, appointed for two years,
R. Lenahan, master plumber, appointed for one year,
Samuel L. Cooper, Commissioner of Public Works,
M. Hanrahan, secretary,

in conjunction with the Board of Health, which consists of the Mayor, Supervisor, President of the Common Council, President of the Water Commission and President of the Board of Police and the Health Officers. The following regulations are now in force:

Plumbing and drainage plans and specifications relating to new buildings in Yonkers must be filed with the Board of Health and approved in writing by the Board or the Health Officer before being executed. The necessary blanks are to be had for same on appli-

cation. Materials and workmanship to be of good quality and character. Separate and independent connection of each house with main sewer required. The choice of glazed earthware with cement joints or iron pipe and lead joints resting with the owner or architect. The house drain, of cast iron, must have a fall of ½-inch to the foot unless otherwise permitted by the Board of Health. If the pipe cannot be carried along the cellar wall or ceiling it is to be laid in a trench cut at a uniform grade, walled up on the sides and provided with movable covers with a concrete base of 4 inches in thickness on which the pipe is to rest. The front wall trap is called for, the fresh air inlet to be at least half the diameter of the soil pipe and opening to the outer air at any convenient place away from window. Chimney flues are forbidden to be used for ventilating sewers, and brick, sheet metal or earthenware flues for the same purposes are not allowed. All changes in direction of lines to be made with ¼-branches and one-eighth bends. Soil pipe to be extended 2 feet above the highest part of roof full bore. Horizontal soil and waste pipes are prohibited, and no traps are allowed at base of vertical soil or waste pipe. All soil, waste, house, drain and vertical lines of vent pipe must be of iron, of the grade known as extra heavy untarred pipe. All of the cast-iron pipes, before the fixtures are set, are to be tested by water, the pipes so filled to be allowed to stand for 24 hours before inspection. Lead calked joints in iron pipe or joints made with iron filings and sal-ammoniac are required. The connection of lead and iron pipe to be made with ferrules and wiped lead joints. The trapping of all fixtures is called for and a vertical line of vent pipe (lead, copper or cast iron) not less than 1½ inches in diameter to be provided, the said pipe to be extended 2 feet above the highest point of roof or branched into soil pipe above the highest fixture. Safes under fixtures to be drained in the usual manner by special pipes not connected with the soil or waste pipe system, the discharge to be either into an open sink upon the cellar floor or outside the house. Cisterns for drinking water are forbidden to be lined with lead, galvanized iron or zinc. If lined, the lining must be tinned or planished copper. The overflow to be trapped and discharged same as the safe wastes.

Rain-water leaders must never be used as soil, vent or waste pipes if connected with a cistern; nor shall any soil, waste or vent pipe be used as a leader. Outside leaders, when connected with house drains, are required to be trapped beneath the ground with a deep seal. If inside the house they are to be of cast iron with lead joints. Steam exhaust pipes not allowed to connect with soil or waste pipes. Cellar and foundation walls to be rendered impervious to dampness. Sub-soil drains to be provided when necessary and no connections to be made with any sewer except by a slant or branch. The plumbing work in all cases to be left open for inspection and the health officer notified.

The penalty for each and every violation of these regulations is a payment of a fine of $100.

TRAPS AND VENTS.

"Smith & Anthony Company, Sanitary Plumbing Specialties," in attractive lettering in two shades of blue on the show windows at 56 Beekman street, find the recently consolidated interests of this Boston house in the charge of C. E. Stevens, in an excellent showroom located right in the midst of the trade in New York. The Sanitas plumbing goods are now being set up to be shown in operation and will be the feature of the showroom well worth seeing when completed. They will also sell the Whirlpool closet of the Beekman salutary system. The Hub steam and hot-water boilers and the Hub hot-air furnaces will be shown by samples. A full line of the Sanitas specialties will be open for the inspection of the dealer. These goods are displayed in the Manufactures Building at the World's Fair.

The *Plumber and Decorator* of London reports that the efforts made to improve the plumbing instruction in the city and guilds of London Institute have been very effective. There has been an increase of candidates in this branch of education, the numbers for the last four years being 547, 569, 684 and 825, respectively. With this increase a diminution has been noted during the last three years in the percentage of failures to pass, the figures being 59 per cent. in 1890, 56.7 in 1891 and 47.2 in 1892. Nearly 1500 candidates are entered for the theoretical and practical plumbing examinations in connection with the institute and the Worshipful Company of Plumbers of London.

Yeoman service is rendered the new plumbers' association in Newark, N. J., by Secretary Alexander Don, though he is hobbling about with a cane, having recently received in an accident a severe bruise on the tendons of his heel.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., for the labor and materials required to put in place all the plumbing and gas pipe in the United States Court House and Post Office Building at Troy, N. Y. Drawings and specifications may be obtained at the office of the Supervising Architect at Washington, or at the office of the Superintendent at Troy.

The following method of bronzing metal articles which are not too heavy for easy handling is recommended by the *Plumber and Decorator:* Thoroughly clean the surface by means of lye and repeated rinsings of cold water, or sandpaper the surface thoroughly clean. If water is used, dry well with a chamois and then heat the article so as to wholly dispel moisture. Now give the surface a coat of shellac, much diluted with alcohol, or a coat of lye. When this is nearly dry proceed in the ordinary manner to apply the bronze, which will adhere to the sticky surface. This plan gives much better results than when the bronze is mixed, because it will not turn black for some time, the reason being that the copper of which the bronze is composed does not come into contact with the metal.

An ingenious automatic switch is now applied to the electric lamps in the guests' room in a hotel, whereby the locking of the room door from the outside (but not from the inside) turns off the lights. Many travelers, it seems, says an exchange, doubtless with the philanthropic idea of helping the business of the local electric lighting company, are accustomed to leave the lamps burning at full head when they vacate their rooms.

Some English gas companies are adopting the use of a new automatic gas meter by which gas is sold to consumers by a penny in-the-slot plan. Some 5000 of these meters are now fixed in Liverpool, and are said to be very popular. They are gratuitously supplied to any house, and by dropping a penny in the slot 25 feet of gas can be obtained, or sufficient to supply one burner with a good light for five hours. The system is to be introduced into Ipswich and other towns, and it is believed that it will have the effect of inducing small householders to adopt gas for lighting and heating purposes in preference to any other medium.

China's Imports.

Very little definite information exists in this country relative to the magnitude of business in iron and steel with China. Some interest, therefore, attaches to a report by Consul J. A. Leonard of Shanghai on the imports into China during the years 1891 and 1892. We have compiled from it the following table:

Imports into China (Net) in 1891 *and* 1892.

Metals.	1891. Gross tons.	1892 Gross tons.
Iron:		
Nail rods	27,000	17,879
Bar	11,824	7,965
Hoop	1,099	727
Sheets and plates	4,094	2,637
Wire	3,768	4,003
Pig and kentledge	3,820	5,779
Old	51,130	41,914
Tin:		
Slabs	4,010	3,986
Plates	1,235	1,149
Lead:		
Pigs	9,200	13,177
Tea and sheet	314	131
Copper:		
Bar, rod, sheets, plates, nails	458	546
Wire	75	84
Unmanufactured slabs, ore	2,277	1,812
Copper ware, unclassed	35	30
Yellow metal, bar, rod, sheets and nails	1,835	1,567
Brass wire	183	188
Steel	3,405	3,181
Spelter	806	2,652
Quicksilver	128	154
Metals, unclassed	297,918	294,451

The total value of the metals imported is placed at $7,254,448 in 1891, and at $7,130,866 in 1892.

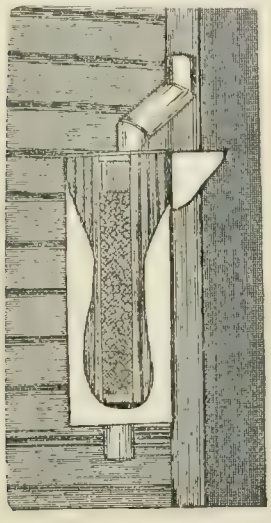
Charles C. Lockstaedt, a mechanical and electrical engineer recently residing in Chicago, is missing, with charges of forgery and obtaining money under false pretenses against him. He is said to have raised above $100,000 by forging notes of the Westinghouse Electric Company, which were negotiated at different Chicago banks. He was the originator of the Chicago Pulley and Hanger Company, and is said to have stocked the shop with machinery unpaid for but used merely as a cloak to give him business standing in the negotiation of the forged notes. It will be recalled that Lockstaedt was the lowest bidder for electric lighting at the World's Fair, through whose instrumentality the Edison Company were defeated in endeavoring to get a much higher price.

Thomas A. Edison thinks the practical speed limit on the horizon of electrical locomotion will be about 150 miles an hour. Before moving heavy trains by electricity he believes that we shall shoot our mail through the country by some electrical device—of telpherage construction, in all probability.

ROOFING AND CORNICE.

The Fox Anti-Freezing Filter and Cut-Off.

We show in the accompanying illustration a view of the Fox Anti Freezing Filter and Cut-Off combined, manufactured by S. S. Fox & Co., Marion, Ohio. The filter is constructed of galvanized iron in two sections, as shown in the illustration, the inner one being corrugated, which, it is said, will not freeze and burst. It is filled with charcoal



Broken View of the Fox Anti-Freezing Filter and Cut-Off.

and gravel, which both filters and purifies the water, making it, it is said, as clear as any well water, and perfectly wholesome for drinking purposes. The cleaning of the filter is an easy matter; the cut-off simply being lifted and swung around into the waste pipe, then the lid is removed and the filter lifted. The charcoal and gravel can then be readily cleaned and put back, or else replaced with new if desired. The cut-off at the top is referred to as being very convenient for washing the soot or dust from the roof before the water is turned into the cistern. The cisterns are made in two sizes—namely, 2 and 4 inches.

The Penn Iron Roofing and Corrugating Company, Ltd.,

of Philadelphia have just received from the press a very large and handsome catalogue of their reeded steel sectional ceiling and side wall decorations, made under the Sagendorph patents. The catalogue is complete in 110 pages, each 10 x 13½ inches, and contains upward of 325 illustrations, many of which attain a size of 8½ x 11 inches. The covers are of stiff paper, the front being handsomely printed in colors and illustrative of the use of decorative art metal plates. The inner page of the front cover announces that the company are not imitators of wall paper designs, all their metal designs being reproductions of ancient carved or molded art and modern art, and include many bold configurations, original in conception, developed by the best artists. The plates illustrated are intended for use in churches, halls, hospitals, dwellings of all classes, and buildings of all kinds. The catalogue is arranged in departments. The first department includes double-reeded steel sheets, and covers molding strips in sizes 1⅓ inches to 4⅓ inches in face and ½ inch to 1¼ inches in depth, suitable for side walls or ceilings; designs of plates, moldings and ornaments, cornices, girder coverings, ceilings, cornices in sections, plates suitable for stileing, paneling or wainscoting, large center ornaments for ceilings, borders, sections of finished ceilings, store ceilings, lavatory interiors, porch and church ceilings and interiors, office and billiard room interiors and a house exterior. The descriptions are very plain and concise. The second department contains some handsome designs of centers and ventilating centers for churches, halls, or large rooms. In the third department are shown wainscoting and side walls in imitation of brick and tile. The fourth department illustrates Italian Renaissance decorations in stairways, wainscoting and dadoes, combination art plates, vestibule interiors and art ceilings. The fifth department shows coves, borders and friezes. The sixth department takes in art steel plates, for ceilings or side walls, in groups, and exhibits many unique designs applicable to all situations. Many combinations of the plates and parlor and store ceiling designs are also shown. The seventh department is devoted to deep molding panels, friezes and complete designs for ceilings with instructions for preparing foundations for ceiling plates and giving explanatory detail drawings. The eighth department includes deep molding plates, stileing sheets and many rich and beautiful combinations. The ninth and last department illustrates the company's extra deep molding plates, which are rich and massive in design, and are 2½ inches in depth of molding, therefore adapted for particularly high ceilings. This department also presents a number of handsome designs for ceilings, side walls and stairways. The remainder of the catalogue is devoted to some plain directions for ordering, preparing, putting up and finishing steel ceilings, and rules governing the mode of application of plates for the best effect. The catalogue should prove very acceptable to the trade.

Sheet-Metal Ornament.

The Metal Stamping & Spinning Company, Grand Rapids, Mich., make an extensive line of sheet-metal ornaments and other specialties, a particular feature claimed for the goods of this company being that their designs are all original. We show in the accompanying illustration an example of the sheet-metal ornament turned out by this firm. In addition to the regular line that they have in stock they state that any special design in ornamental work can be done on short notice by sending them a sketch or drawing or sample of the design wanted.

Sheet-Metal Ornament.

FLASHINGS.

Marlin & Co., Allegheny City, Pa., are just adding another building, 25 x 50 feet and two stories high, to their sheet-metal working plant. Metallic skylights, galvanized-iron cornice, Standard expanding water conductor and fasteners and eave troughs in 8 foot lengths, with detachable couplings, find a liberal patronage in the trade. Another field in which they have a grow-

ing demand is the sheet-iron work for heating and ventilating where either pressure or exhaust fans are used and for blowers. A fine piece of work recently turned out was a T branch made of heavy galvanized iron, the main being 43 inches in diameter and each of the branches 34 inches in diameter. It was so made as to appear like two circular elbows growing out of one pipe, the joints being smooth and the curves being uniform. Some of the plants and buildings for which they have done the ventilating sheet-iron work are the Pittsburgh Locomotive Works, the Bindley Hardware Company's building, the Newell Hotel, the Fuel Gas & Mfg. Company's plant, the rolling mill of Shoenburger & Co., the rolling mill machinery plant of Robinson & Rea and the Braddocks wire works of J. Painter & Sons Company.

AN ATTRACTIVE CATALOGUE is issued by the KNOX & STONIER Architectural Sheet Metal Ornament Company, Toulon, Stark County, Ill. The catalogue is 9½ x 12 inches in size, bound in fancy paper, prettily colored. The interior pages (some 50 in number) contain an extensive series of illustrations of sheet metal work of their manufacture. Some 12 pages are given up to enrichments, friezes, &c., of various kinds; crestings follow, then diapers, &c.; then come panels and panel ornaments, shelves, leaves, finials and urns, &c., the catalogue closing with a few examples of sheet metal statuary. In connection with the illustrations are given the numbers of the articles, sizes and prices.

THE J. S. BROOKS MFG. COMPANY, Brooklyn, N. Y., who are putting on tin roofs on a system patented by J. S. Brooks, and illustrated in *The Metal Worker* a few months ago, state in a letter that they find the work greatly facilitated by the use of the quadruple roofing folder made by M. E. Hastings of New York Mills, N. Y.

W. G. HYNDMAN & Co., Cincinnati, Ohio, take pride in having designed and had constructed under their supervision all the machinery used by them in the manufacture of iron and steel roofing and siding, whether flat or corrugated. Being among the oldest manufacturers in this line of business, the industry has ever found them progressing with its growth.

POWER AND HAND MACHINERY for the tinner's use in working sheet metal is made by J. M. Robinson & Co., Cincinnati, Ohio, and when their line of cornice brakes, flanging machines, presses and rolls do not meet the requirements, special machinery to accomplish the desired result is designed and constructed. In addition to making machines they stamp up special designs from sheet metal for houses who require goods of that character.

WRITING from Murree, India, F. C. Constable relates that during a recent hailstorm corrugated iron roofs were in many cases perforated by the hail. As an ending to this extraordinary tale he says he measured one hailstone four hours after the storm and found it to be 4½ inches in circumference.

A NEW CATALOGUE from Bowers, Galpin & Co., Binghamton, N. Y., appears in a light olive cover printed in dark blue, apprising the trade that their facilities have again been increased and several new articles are presented that are of the class that sell on their merit. In shape, the pamphlet is well adapted for illustrating galvanized iron. IX and IC terne plate and patent "Never Slip" eave trough, which is sold in seamless 10-foot sections, galvanized and terne plate gutters in long sections and various styles occupy several pages. Galvanized iron ridging and corrugated octagon and square conductor pipe are shown in long sections and elbows and fittings in variety. Standing seam steel roofing is also shown by illustration. Specially prepared circulars giving full instruction and information of any of their specialties are furnished on application.

AT THE INVITATION OF BRUCE & COOK, a number of roofers in the vicinity of New York attended the exhibition of the quadruple roofing folder by the patentee, M. E Hastings of New York Mills, N. Y. Being a practical roofer, he showed that considerable time could be saved both in the shop and on the roof by the use of his machine.

GEO. DANBY of the American Sheet Iron Company, Phillipsburg, N. J., was in New York this week and reports that the month of July has been used to thoroughly overhaul their engine, but next Monday the mill will start running full, making three turns a day.

DURING the first half of this year sheet iron for roofing purposes, guaranteed not to exceed $\frac{6}{10}\frac{4}{0}$ pound per superficial foot was sold f.o.b. Ohio mills at $2.65 per hundred pounds, terms, 60 days' note or acceptance, or 2 per cent. discount for cash in ten days. This price was made by a mill possessing a good reputation and was considered "suicidal" among the trade. To-day any roofing concern having cash at their disposal would not have to hunt many days to find a mill ready to accept specifications at a very much lower figure.

T. S. CASEY and GEORGE E. DAY have united forces under the firm name of Casey & Day and will hereafter represent, as selling agents, the Riverside Iron Works of Wheeling, manufacturers of Steel Pipe; the Globe Roofing Company of Cincinnati, makers of Sheet-Metal Roofing, and the Newport Rolling Mill Company of Cincinnati, manufacturers of light Sheets. Mr. Casey has represented the Riverside Iron Works in Chicago for 17 years, while Mr. Day was manager of the Hazen Company of Cincinnati for 12 years, so that both are very widely known in the Western Iron and Hardware trades. Their offices will be located in suite 445 The Rookery, Chicago.

A writer in a London magazine records the results of calculation made by him of the weight and measurement of the sea. According to his computations the number of gallons in the whole sea is 373 trillions (million million million), which, if it could be poured away at the rate of 1000 gallons a second, would take nearly 12,000 million years to get rid of. Supposing the sea to be formed into a round column reaching to the sun, the diameter of the column would be nearly 2½ miles. The Pacific would form 53 million miles of its total length of 93 million, and the Atlantic 18 million.

Plaster-of-paris has lately come into vogue in France for flooring, in place of wood or tile. The French, who have carried the art of hardening plaster to perfection, use, says the *National Builder*, six parts of good quality plaster intimately mixed with one part of freshly slacked white lime, finely sifted. This mixture is then laid down as quickly as possible, care being taken that the trowel is not used on it for too long a time. The floor is then allowed to become very dry, and is afterward thoroughly saturated with sulphate of iron or zinc, the iron giving the strongest surface, the resistance to breaking being 20 times the strength of ordinary plaster. With sulphate of zinc the floor remains white, but when iron is used it becomes the color of rusted iron; but if linseed oil, boiled with litharge, be applied to the surface, it becomes of a beautiful mahogany color. Especially is this the case if a coat of copal varnish be added.

The quickness with which our American hustlers can work when caught in the horns of a dilemma was well illustrated at Muncie, Ind., a few days ago, observes a Western exchange. The material for building 1 mile of electric railway arrived in that city, after having been "lost" on the railroad for 12 days, at 4 o'clock Monday morning. The rails and other materials were unloaded and hauled from the cars, over a mile, where the work of road making began. This was kept up until 12 o'clock the next day, when, after just 32 hours' work, 4800 feet of track had been laid, the track lined up, surfaced, dirt thrown back in, the poles erected, the trolley wires strung, the feeders tapped in and a car started over the track. More than 8000 persons were carried to the baseball game over the road that afternoon.

Yet another cement for pipes is chronicled. The *Safety Valve* recommends it as specially valuable for filling up leaks, such as a blow-hole in a casting, without the necessity of removing the injured portion. The cement in question is composed of 5 pounds Paris white, 5 pounds yellow ochre, 10 pounds litharge, 5 pounds red lead and 4 pounds black oxide manganese, these various materials being mixed with great thoroughness, a small quantity of asbestos and boiled oil being afterward added. The composition as thus prepared will, it is said, set hard in from two to five hours, and possesses the advantage of not being subject to expansion and contraction to such an extent as to cause leakage afterward, and its efficiency in places difficult of access is mentioned as being of special importance.

The mica industry of South Australia has received a fresh impetus recently. Several parties have started from Adelaide to the McDonnell Ranges, where large deposits of the mineral are found, to re-open some of the old workings. The reasons before which caused their temporary abandonment were the difficulty of transportation and the fall in the price of mica. It is now thought that these have been obviated. The mica has to be carried 500 miles on camels to the nearest railway station, Oodnatta, the present terminal point of the overland railway now in course of construction by the Government. Thence it is transported by rail to Port Augusta and shipped to the most profitable markets. The demand is said to be very good at present.

An International Petroleum Exhibition, dealing with oil, oil illuminants, oil heating and cooking apparatus, oil motors and apparatus and appliances, is to be held at Bolsward, in Holland, at the beginning of this month.

STOVE TRADE NOTES.

The Future of the Hot-Air Furnace.

By A. W. Glessner,

President of the Excelsior Steel Furnace Company.

PROFITS ON FURNACES.

In conversation with a furnace dealer in a growing town in Illinois, a short time since, the gentleman complained bitterly of the low prices at which furnace contracts were being let in his place, and said that he was being "knocked out on all sides"—not only by furnacemen but by steam contractors as well. I thereupon asked him what profit he thought he was entitled to on a furnace job for an eight-room house, and he promptly replied: "Fifty dollars, at least." "Well, then, what do you figure the cost of the furnace and materials on such a job?" He figured a moment and said: "About $125." "And the labor?" "Oh, $25 more." "Then," said I, "on an investment of $150, all told, you consider yourself entitled to a profit of at least $50?" To which he replied that he did. Further discussion of the subject revealed the fact that he was buying his furnaces on time, and not taking the discount, and that the cash outlay, instead of being $150, was less than $100. He was then asked if, in view of the general trend of prices downward and the narrowing margins of most lines of goods handled by him, he was not expecting too large a profit on the furnace department of his business, and after some beating about the bush he admitted that he ought to be satisfied with a smaller sum, but claimed that, as far as his past experience went, a dealer was not justified in handling a furnace job for less than the sum originally named.

Doubtless many other dealers hold the same opinion; but while they hold out for higher prices and larger profits, other and more progressive dealers are coming in and taking jobs at closer yet safe figures, and helping instead of hindering the furnace business.

LARGE PROFITS.

Dealers in all lines have certain articles on which they expect and intend to make large profits, owing to a lack on the part of the buyers as to the intrinsic value of such articles, and dealers fight vigorously every decline in the price of the same, but we are on the downward course in most lines, and it is useless to expect to realize war prices and profits on furnace work. A furnace job should yield a fair margin to the dealer, but it should not be expected to pay double and thrice the percentage of profit that other articles do. Furthermore, a furnace differs from most other articles in the stock of a dealer, inasmuch as it is a constant source of profit, for once the dealer puts in a furnace for a man he has a hold on that man, and if he treats him properly he will have his steady patronage, as the customer must come to him for repairs and cleaning out the apparatus, and will naturally place his total trade with the dealer. This phase of the furnace trade has not been sufficiently considered by the dealer, and if the value of the furnace trade as an adjunct to the general business of the dealer is admitted, he can certainly afford to seek furnace contracts at a fair margin.

EXCESSIVE PROFITS.

One thing is reasonably certain, and that is that excessive profits cannot be realized from furnaces in the future, and on the other hand there is no reason for thinking that prices will go to a point which will fail to yield a satisfactory profit to the dealer who buys carefully and understands the business.

(*To be continued.*)

The Belleville Stove Works.

We have received from the Belleville Pump & Skein Works, proprietors of of the Belleville Stove Works, Belleville, Ill., a copy of an illustrated catalogue of St. Clair stoves and ranges, which they have just issued. It is a work of 116 pages, profusely illustrated with well-executed cuts and bound in flexible covers carrying a side title in old gold, silver and green upon a maroon groundwork. Following the presentation of prices at which stove repairs can be supplied, a statement of terms, remarks concerning breakages and freight overcharges on stoves, ranges and castings, together with directions for setting up and operating stoves, attention is invited to the Acme wrought-steel range, made with six boiler holes in the top surface, large flues, ventilated oven, swing feed door and elevated warming closet. Following this in turn we find the St. Clair A, which is a new six-hole range of novel decoration and embodying features which render it durable and satisfactory in operation. This stove is shown in several varieties, as is also the Brilliant St. Clair, which is intended for soft or hard coal or wood. The St. Clair B, the Royal St. Clair, the Grand St. Clair, the Model St. Clair and the Magic St. Clair, the latter being a four-hole wood range, are some of the other goods illustrated and described. The cook stoves occupy a number of pages, and are presented under such names as the Perfect St. Clair, a new first class four-hole stove for soft or hard coal or wood and having stove back guaranteed for five years; the St. Clair A, the Home St. Clair, the Advance, the St. Clair, the Famous A, the Superb, which is a new series of cook stoves embodying the latest features; the Family St. Clair, the Belleville, the Challenge, the Reliance, the Matchless and the Lily, the latter being a cheap cook intended for burning wood only. The place of honor among the heating stoves is given to the St. Clair Oak, made with double fire pot and having cone center grate, sheet-steel jacket and nickel trimmings; the St. Clair Oak, fitted with ventiduct, which is made strong and not likely to get out of order; the Cornelia, a base heater with magazine and full return flue; the Peerless, a very pretty open Franklin stove with round fire pot; the Vulcan, a heavy cannon stove; the Merit, a new laundry stove; the Graphic St. Clair, a well-made cottage parlor stove; the Parlor Queen, a handsome Todd for burning wood; the Imperial, an attractive box stove, and the Pet, a unique construction for burning coal or wood. A long list of hollow ware, tin trimmings, elbows, drums, stove pipe, dripping pans, tea kettles and miscellaneous goods complete the catalogue.

The Scranton Stove Works.

One of the neatest catalogues coming from the Scranton Stove Works of Scranton, Pa., which it has been our pleasure to examine is that which they have issued for this season's trade. The frontispiece is a bird's-eye view of the company's new works, of which they have just taken formal possession and which the rapid increase of business rendered necessary. A somewhat lengthy description of these works was given in our issue for last week, from which the reader can gather an idea of their extent and capacity. In the catalogue before us attention is particularly invited to the line of goods made under the name Dockash, of which the 1893 series of six-hole ranges occupy the leading place. This stove is fitted with the company's new hypocaust ventilated oven attachment, and the fire box is at the right hand as one stands facing the oven door. The ornamental features are neat and effective, while the construction is of the latest style. Following this construction we find the Z series of Dockash ranges, embodying essentially the same features as are found in the stove just described. The Z series is made in the usual modifications, several of which are illustrated. There are also shown patterns of the Dockash range for 1890, 1888, 1887 and 1881, all of which are offered in a variety of styles and sizes. We also notice the 1892 pattern of the X series of Dockash ranges, having six boiler holes and made in five sizes. Other goods include the Dockash Good Morning, Dockash the Great, Easter Dockash, Easter, Wyoming and Lackawanna. Under the name Dockash the company offer a four-hole range of attractive design, embodying the latest features; also a six-hole range known as the Dock Corn. The Dockash steel range, the Longfellow, Universal, Oakwood and Recorder cook stoves are some of the other goods to which attention is invited. The heaters are creditably represented by the Grand Dockash, a handsomely treated square parlor stove for burning hard coal. It is made in four sizes and has round Dockash grate and either solid or sectional fire pot, as may be desired. A foul-air ventilator is provided, which takes the air at the base and discharges it in the back flue at the elbow. It is mounted with a new upper section automatic magazine cover, nickel corner brackets and large flues. It is shown in the catalogue with and without the oven attachment. The Grand Garnet, made in three sizes plain and two sizes with oven, is another attractive heater for burning hard coal. We also notice

the Dockash and Camilla cabinet parlor stoves, the Dockash surface burner, the Central Sun round base burner, the Lackawanna cannon stove and the Office King, a heavy globe stove. One page is devoted to a sectional view of a stove showing the hypocaust system as employed in connection with the Dockash goods. Other features of the catalogue include directions for ordering repairs, list of plates which can be supplied for obsolete stoves, an illustrated description of the Dockash grate and an alphabetical index. The printing of the catalogue is in black upon a good quality of paper, the matter being relieved by an ornamental corner piece in red, consisting of a *fac-simile* of the company's trade-mark in connection with their corporate name. The binding is in flexible covers of such a shade as to form a pleasing contrast with the black lettering employed in connection with the side title.

Southard, Robertson & Co.,

with office and warerooms at the corner of Water street and Peck Slip, New York City, and with foundries at Peekskill, N. Y., favor us with a copy of an attractive catalogue which they have issued relating to their lines of stoves and ranges. These goods are made under a variety of names, prominent among which may be mentioned the Phœnix, a six-hole range, embracing the latest improvements. The constructive features include large oven, burnished edges, extra heavy covers and double supported center pieces, Smyth's patent rotary triangular grate, large ash pan, patent oven door opener, Read's patent draft damper and extended fire pot for wood. There is also shown the New Rocket, a new six-hole range embodying the modern features; the Servia, a medium grade six-hole construction made in several styles and sizes; the Columbus, a substantial low priced six-hole range; the New Jockey, a neat five-hole range; the Pansy, the Wren and the Bono. The cook stoves are represented by the Standard for burning coal or wood; the New Opera, a new addition to the company's assortment; the Magnet and the Yale. The heaters include the well-known Madison Square full revertible flue parlor stove, made in three sizes and decorated in a tasteful manner; the Columbus, made direct draft and also full revertible flue; the Regal, a direct draft round base burner; the Exeter, a well made sheet-iron surface burner; the Flag, a neat cylinder stove; the Aurania, a recent addition to the company's line of open Franklin stoves; the Cottage Home, the Ingle, the London, a heavy cannon stove, shown with and without sheet-iron top; the Senate a member of the same class, and the Lotus, a cheap laundry stove. A comprehensive index and a list of stoves for which repairs can be furnished are features of the catalogue. The volume consists of 96 pages and is bound in black covers with side title in silver lettering.

A POSTAL CARD is being sent out by Faith Belson & Co., Philadelphia, bearing the following information: "We take pleasure in informing you that we have removed to our new and spacious building at 229 Market street, where we hope to be favored with a continuance of your patronage." With the increased facilities gained by the change, orders for stoves, gasoline goods and refrigerators will be filled with promptness.

The Maker, Jobber and Seller of Stoves.

From D. T. S.—So many things come up to any one who has had a long experience in every branch of the stove business that a few rambling observations may not be without interest. That the jobber has the best of it I think has been demonstrated by the example found in every trade center. He either buys his stoves complete for so much apiece or has the castings laid down at his door at so much per pound, and can have them mounted by piecework, so that he can say positively that stove cost so much. The foundryman has strikes, breakdowns, unpopular patterns and such items to figure in, so that at best his cost is an estimate, and too late may be found all wrong. The recent disposition to demand more wages by molders regardless of the fact that in no other branch of trade any advance was being made, is something that didn't bother the jobber. Stoves cannot be advanced in price so as to advance molders' wages unless other workmen are getting an advance. Under the present conditions to advance the price of stoves would stagnate trade.

I was talking to a retail dealer only a few days ago and he remarked that two-thirds of his sales of stoves were to people who did not need a new stove because the old one was worn out, but they bought because they happened to see something that pleased their fancy, or an impression had seized them that they had used the old stove long enough, even though it was capable of doing good service for years. He added that to advance the price on stoves would stop their buying and said that the other one-third cannot afford to pay more. One dealer stated that the spring trade was flat; another said he had done less than he had in 12 years, and another that he had had his dullest spring in 25 years.

Fortunately the stocks in the dealers' hands are light, but if the coming winter should prove mild can the same be said next summer? The prospects for a good fall vary with each prophet. If there are not enough goods to go round the maker will be blamed by both the jobber and the dealer, and if there is a surplus on hand at the end of the season the jobber will congratulate himself that it is distributed between the maker and the dealer.

The Excelsior Mfg. Company.

An illustrated stove catalogue, of nearly 200 pages, bound in black covers with silver lettering, reaches us from the Excelsior Mfg. Company of St. Louis, Mo., and with branches in Denver, Col., and Portland, Ore. A noticeable feature of the volume is the printing, which is in two colors, forming a pleasing contrast. Another feature is the back title, consisting of the name and address of the company and the date of the catalogue. By means of it the dealer is enabled to readily identify the volume without trouble, even when filed away with other trade literature. The opening pages of the volume contain an announcement to the trade and the public at large, with reference to the discovery by Mr. Filley regarding the wire-gauze oven door; some remarks pertaining to breakages and freight overcharges on stoves, ranges and castings; a statement of terms; a description of the hot-water center for pressure boilers and other information of general interest in connection with heating and cooking operations. As our readers are well aware the leading products of this company are known under the name Charter Oak, and it is natural, therefore, to find a large number of pages given to these constructions. The first one considered is the Charter Oak four-hole cook, made in six sizes and a variety of styles. The next is Filley's New Brand Charter Oak cook stoves and ranges, which have large ovens, reversible long centers, round edges, outside stationary oven shelves, patent oven-door openers and other modern features. The Royal Charter Oak for wood only; the Charter Oak range adapted for burning the same kind of fuel; the Hotel Charter Oak for wood; the Charter Oak for soft coal; the Grand Charter Oak for hard coal; the Hotel Charter Oak for soft coal, and the Messenger and new Mabel cooks for burning wood only are also presented for the consideration of the trade. In connection with each stove is given the number of sizes in which it is made, the list prices, code words, number of holes in the top surface, the size of the oven and the weight. Filley's Challenge steel ranges for hard coal, soft coal and for wood are also illustrated and described, in connection with which is a table giving the sizes and prices of the different styles made. In the line of heaters we find the Royal Charter hard coal base burner; the Parlor Pride for hard coal; Filley's Charter Oak, a handsome heater made in one size only; the Boaz, a round soft coal base heater, which has become very popular with the trade; the Young Hickory, an oak stove for coal and for wood; the Columbia Oak for burning coal; the Irondale, a cannon stove for coal only; the Wasp; the Pluto, members of the same class; the Opal, a Franklin for hard or soft coal; the Kirkwood, a richly treated cottage, direct draft and revertible flue; the Astoria, a handsome Todd, together with a line of box, laundry and tailor stoves, fire-place grates, charcoal furnaces, waffle irons, boilers, &c. The closing pages of the publication are given up to lists of stove hollow ware, stove trimmings, broiling ovens and sectional cuts of a cook stove and range so numbered with regard to their various parts as to facilitate the ordering of repairs. The volume is arranged in an attractive style and is issued in a form which is likely to find favor with the trade.

ODD PLATES.

IN THE REVIEW of the catalogue of the Peninsular Stove Company, which appeared in our issue for July 22, the new parlor heater known as the World's Leader should have been described as a self-feeding base burner adapted for using hard coal, coke or natural gas. It has heavy ribbed revolving fire pot, which can be removed and replaced through the front mica door, large revertible flues and draw center shaking grate. The ornamentation involves the judicious use of nickel, which, in combination with the black iron of the stove, forms a pleasing contrast. The World's Leader is made in four sizes, with fire pots measuring respectively 10, 11, 12 and 14 inches. The manufacturers refer to the stove as being elegant and attractive in appearance and possessing many new features not found in others of its class.

COMMODORE M. B. MILLS of the Michigan Yacht Squadron, handsomely entertained the employees of the Chi-

cago office of the Detroit Stove Works aboard his steam yacht "Grace," on Saturday of last week. Commodore Mills issued special invitations for the occasion, which was an enjoyable one in every way. The weather was delightful for a cruise on the lake, and those who participated enjoyed a trip which will long be remembered. Among those who were able to accept the hospitality of the Commodore were Mr. and Mrs. Dodson, Mr. and Mrs. Williams, Mr. and Mrs. Schall, John Sheppard, Jr., Miss Sheppard, the Misses Lyman, Miss Deseau and Messrs. Nichols, Ambler, Johnson and Sewall.

WE HAVE RECEIVED with the compliments of Cribben, Sexton & Co., of Chicago, Ill, a memorandum book of a size which permits it to be easily carried in the vest pocket. The covers are of colored paper and carry advertising matter relating to the Universal stoves and ranges which are made by the company named. The third page of the cover gives rates of domestic postage, while the fourth page carries the names of the cities, both domestic and foreign, in which the company have agencies. Across the top of each blank page intended for memoranda is an inscription calling attention to some feature of the Universal stoves and ranges.

THE DEMAND for the goods turned out by the Round Oak Stove Works of Dowagiac, Mich., continues of a gratifying character and orders are received by the company from all sections of the country as well as from foreign parts. Among their recent shipments was a bill of goods to Corea.

WORK WAS RESUMED Monday, July 31, at the works of Fuller & Warren Company, Troy, N. Y., a full force being employed and all departments of the plant are in operation. Treasurer Mackey states that he expects that the stove foundry will now run nearly full capacity during the fall and winter, without interruption. The announcement that the works would start up was received with great joy by the many workingmen employed at the Clinton Foundry. The concern have over 700 men on the pay roll when the plant is in full operation. This, coupled with the fact that the other Troy foundries are doing a good business, is reassuring at least.

IT IS to be regretted that the New York and New England Agricultural Association of Albany, N. Y., is not to hold its fair on the grounds in that city this fall. It will be remembered by the readers of *The Metal Worker* that during the past two years the attractiveness of the exhibitions given by this organization have been greatly enhanced by the showing which the Albany and Troy stovemen made. "Stove Hall" was the most attractive building on the ground — of course coupled with "Andes Hall," the building of the Phillips & Clark Stove Company of Geneva and Troy, N. Y. This year, as the fair people are to hold their exhibit in Rensselaer County, N. Y., it is not in the least probable that the stovemen will take a part, as the conveniences are not at hand, and the location of the fair is not where they would care to go at quite an expense to show their lines of heating goods. If they do make any showing it will probably be through retail dealers.

WE HAVE RECEIVED from the Michigan Stove Company, as a sample of the advertising novelties which they are now distributing, a tin cake cutter which is made in the form of the Garland trade-mark. The cutter forms the shape of the trade-mark in the edges of the cake, while the top lettering impresses on the cake the legend "Garland Stoves and Ranges;" also a very pretty copybook with lithographed copies throughout, two being arranged on a page. The sentences given to be copied consist of references to Garland stoves and ranges, so that it is presumed a very warm feeling toward these goods will be inculcated in the rising generation.

A PLEASANT LETTER from Wood, Bishop & Co., Bangor, Maine, states that their house was established in 1839, and that they can point with pride to numerous churches which they have acceptably warmed in the past 40 years. It very naturally follows that the Monitor wood furnace was used and set with a hot-air grate directly over it, so that the churches were warmed quickly when the mercury was 20° below zero. These furnaces are distributed through Maine and many other States.

THE PENN DIAMOND is one of the new things which the Mt. Penn Stove Works, Reading, Pa., present with pride to the trade. Taken practically, it has the latest improvement of the duplex grate, can be taken apart in the middle for convenient handling, heats a room above or acts as an air circulator, taking the air from the floor, and has a mica illumination so full and brilliant that it might be called electrical. These are specially prominent features among those generally recognized as essential. Artistically, mica, iron, nickel and bronze have been used by the designer to produce a stove with much beauty to attract the buyer. It is put on the market as strictly high grade, and all are invited to make the practical test of running it this fall for a leader to verify the claim. It is made in four sizes, the fire pots measuring full 12, 13, 14 and 16 inches in diameter.

THE SECRETARY OF STATE of Illinois has licensed the incorporation of the McManis Stove Company, with office at Chicago, Ill. The organization is for the purpose of manufacturing heating stoves, as well as heating and lighting appliances, and the capital stock is placed at $200,000. The incorporators are Charles R. McManis, Richard C. McManis and W. I. Culver.

F. E. BROWNE, 314 and 316 South Spring street, Los Angeles, Cal., sends us a circular illustrating and describing Browne's steel dome furnace, so made, it is claimed, as to be especially adapted for the climate of Southern California. It is constructed with a small fire pot with large radiating drum. A deflecting damper is employed to force the products of combustion against the radiating drum instead of allowing them to pass directly to the smoke pipe. It is encased in Russia iron, and the maker states that it can be used on any floor with entire satisfaction. It is intended for using soft coal or wood as a fuel. It is made in three sizes, the smallest being large enough for a six to nine room house, the second size for a ten to twelve room house, while the largest size is said to be of sufficient capacity for heating churches and halls. We also have from Mr. Browne an illustrated circular of the Orient lamp heater, consisting essentially of a drum, in which is placed a mammoth lamp constructed of brass and finished with nickel. The lamp has a capacity of one gallon of oil, and burns with a white flame 5½ inches in diameter. The base or stand holding the lamp is made of cast iron, nickel plated and highly polished. The reflector is also nickel finished. The ornamental top and urn are made of brass and handsomely nickeled. The top and urn may be readily removed, thus permitting the heater to be employed for cooking purposes.

THE FULLER & WARREN COMPANY of Troy, N. Y., are sending out a series of World's Fair cards printed in colors. Upon one side of each card is a picture in which some of the World's Fair buildings are features of the background, while the foreground is occupied with representatives of various nationalities, who appear to be interested in the antics of a personage dressed in the garb of Uncle Sam, standing upon a huge ball or globe, pasted upon one side of which is the inscription "F. & W. Co. Guaranteed Stoves." Upon the opposite side of each card is advertising matter, to the effect that the Fuller & Warren Company are the "largest manufacturers of stoves, ranges, furnaces and hot-water heaters in the world." It is also stated that over 2,000,000 Stewart stoves have been made and sold.

THE ART STOVE COMPANY of Detroit, Mich., have just built an addition to their mounting department, which renders it complete in all respects. New ideas in the way of lighting have been introduced, and the company are fully equipped for the fall trade. Orders are reported greatly in excess of last year. The company have been granted a patent on the flue construction of their oil heaters, and it is used in connection with all styles and sizes. These oil heaters are known as the Laurel and are meeting with a gratifying demand.

THE PENINSULAR STOVE COMPANY of Chicago are distributing to those visiting their display at the World's Fair grounds a card printed in the colors of Spain and America. The card tells where the headquarters of the company are located in Chicago, Detroit and Buffalo and extends to visitors a cordial invitation to call whenever in the cities named. Down in the left-hand corner of the card is a *fac-simile* of the company's trade-mark.

"I WAS CONVERSING with a stove man the other day," says a correspondent, "and, as usual, he became decidedly enthusiastic over his own special make of heating goods, and rhapsodized continually on the wonderful feats performed by a certain range. Then he proceeded to tell how much work the aforesaid range would do with a little fuel. With all the sobriety of a judge on the bench he related how this range was tried by a family who had just purchased one. He said that all they did was to put in the end of an old broom to start the fire; then they used the broom-handle gradually and baked a pan of biscuit or a loaf of bread, I forget which. When I smiled, he offered to take affidavit that such was the case. I expected to hear him begin to tell about how he cooked a corned-beef and cabbage dinner with a piece of brown paper as fuel in this wonderful range, so I changed the subject."

ALTHOUGH it is usually the custom of the large molding shops at Albany, N. Y., to close down during the very warm weather, owing to the season being over and there being a lack of demand for stoves, and also to the difficulty experienced in keeping the temperature of the shops at a bearable point, the firm of Rathbone, Sard &

Co. have concluded to continue operations the year round without abatement. The demand for their stoves has been large and a corresponding demand is anticipated for the future. Of course, most of the work which is now being done is what is termed "stock work," and there will be no return on the investment for some time to come. Their employees are grateful for this decision on the part of the company.

THE FOUNDRY of Oscar G. Thomas, Taunton, Mass., started up a few days ago after a shut down of two weeks for the purpose of making extensive repairs to the plant. A new cupola has been put in, the roofs of the various buildings have been repaired and a general renovation has been in progress. The foundry is running with a good supply of work on hand, and it is intimated that the force is likely to be increased in the near future.

AS MENTIONED last week the Scranton Stove works poured the first heat at their new plant on the afternoon of Tuesday, July 18. The cast was successful in every way, 3½ tons of iron being run into the molds. J. A. Lansing, president, and A. C. Fuller, secretary and treasurer of the company, were present on the occasion named. The works will probably be in full operation in the course of a week or ten days, and all departments will be run full capacity. Each department is under the charge of foremen specially qualified for the position, Thomas Sheppard having charge of the mounting room, W. H. Huber of the foundry, George Frank of the nickel shop, Henry Pillips of the cleaning and milling rooms, James Beattie of the stocks and supplies, Samuel Smith of the engine and machinery, and B. Woodhull of the pattern shops.

THE NEW ENGLAND STOVE COMPANY of Taunton, Mass., are in active operation and a good trade is in progress.

A. E. HAUSER of the Marcy Stove Repair Company, New York, looks better for a month of recreation, a portion of which was agreeably spent at the World's Fair city, where he remarked the fact that notes were withheld and silver invariably given in making change.

THE ABRAM COX STOVE COMPANY of Philadelphia, Pa., are getting things into shape in their new building, which has a frontage of 500 feet on American and 126 feet on Dauphin street, and which has cost in the neighborhood of $80,000. The first floor of the building is intended for shipping purposes; the second and third floors for the mounting department, as well as for storage, while on the fourth floor will be a tin shop and on the fifth floor the pattern shop. The top floor will be used as a warehouse. The salesrooms will be on the second floor, where a space of 35 x 150 feet will be fitted up for the display of goods.

THE SOMERSET STOVE FOUNDRY of Somerset, Mass., resumed operations on Monday, July 31, after a shut down of three weeks for the purpose of making necessary repairs.

A ST. PAUL JOURNAL states that all the cooking in the Minnesota Club House in that city is done by electricity, and fastidious members declare that they never knew before the joys of perfectly broiled chops and steaks. The electrical ovens used are described as wonderfully neat and convenient, and very simple withal. They are made of Russia iron, lined with wood and asbestos, which prevents radiation of heat into the room. The heating plates are so arranged that the heat can be applied either from above or below, or both, at the same time, this and the degree of heat being controlled by a switch placed on the outside. An incandescent lamp lights the oven, and in the front is a glass door through which observations may be taken of the progress of events inside. The thermometer is attached to the top of the oven, showing the exact degree of heat.

GAS STOVES are becoming more common in France. The Paris Gas Company in their report for 1892 show 139,338 stoves lent by them to customers, an increase of nearly 15,000 over the previous year.

THE LATEST SOUVENIRS issued by the Richmond Stove Company, Norwich, Conn., have a much greater value than the ordinary run of advertising matter. They are leather pocket books, of the card-case variety, bearing no reference to the publishers, except the neatly printed name of the Richmond Stove Company in small letters on the inside. The card case is 4½ x 3 inches, divided into three compartments, and is finished with much care and neatness throughout. It is an article for use rather than for decoration, and as such, we believe it will serve to keep the name of the Richmond Stove Company in the minds of many.

THE HOWARD FURNACE COMPANY of Syracuse, N. Y., have issued an exceedingly attractive catalogue in which is given a description, together with other information, relating to warm-air furnaces and combination heaters, which are manufactured under the patents of Charles D. Howard. The make-up of the little volume is of a high order, the arrangement and mechanical execution being above the average. A short chapter is given on the subjects of heating and ventilation, following which are full descriptions of the leading goods made by the company named. The heaters are illustrated by means of sectional views, so that a perusal of the matter presented cannot fail to give the reader an idea of the plan of construction employed and the improved and desirable features incorporated. The company have branches in Boston, Mass., New York City, Grand Rapids, Mich., and Toronto, Canada.

THE JEWEL TALLY-HO COACH of the Detroit Stove Works, which makes daily trips between the company's Chicago headquarters and the World's Fair Grounds, has been carrying a large number of passengers, representing nearly every section of the country. Among those who more recently enjoyed a ride may be mentioned the following: Julius Rieth and mother, and Miss Jennie Rieth of Lansing, Iowa; Mr. and Mrs. Geo. Koch and Elmer Koch, Rochester, N. Y.; Maud Eiseman, Sioux City, Iowa; Mrs. L. Goldsmith, A. H. Gauff, R. J. Miller, Mr. and Mrs. F. H. Fogarty, Mr. and Mrs. H C. Brown, Mr. and Mrs. Sam Pashley, Edward Hutchinson, C. J. Gunderson, Miss Ollie Gunderson, Miss Dorothy Detlie, Miss Estelle Runyan, Mrs. L. Cohen, Miss Bessie Cohen, Mrs. Adam Gauff, Mrs. W. T. Goss, Miss Burbank, Mrs. T. W. Burbank, F. J. Magerstadt and friends, Miss Whiting, Mrs. W. J. Manning, Mr. and Mrs. H. C. Clayton and daughter, S. A. Sydam, Mrs. F. C. Storey and two friends, Mr. and Mrs. Aaron Ehrlich, M. Kaufman, all of Chicago; Mr. and Mrs. L. Rosenberg, Lillian Barbour, Nellie Barbour, H. Barbour of South Chicago, Ill.; C. A. Heergaard, Mandan, N. Dak.; Jno. Sheppard, Mrs. Sarah Sheppard of Penn Yan, N. Y.; E. T. Curry, Clinton, Ill.; Mr. and Mrs. W. H. Kirk and son, Mr. and Mrs. Jno. Swain, P. E. Olsen of Minneapolis, Minn.; H. E. Trilling, Mr. and Mrs. F. J. Robertson, Manasha, Wis.; Mrs. Horace M. Jones, Aurora, Neb.; W. G. Bachman, Decatur, Ill.; Mr. Davis of Pinkerton & Evans, Monmoth, Ill.; Mrs. H. W. Peak and party of seven, Maj. F. M. Burrows, Fort Worth, Texas; G. B. Gunderson, H. U. Furber, Mr. and Mrs. McClarey, the Misses McClarey of Detroit; Jos. Rohrheimer, Shamoken, Pa.; Mrs. S. K. Livingstone, Tamaqua, Pa.; Mrs. Hattie Benjamin, Kansas City, Mo.; W. Barnette, New Orleans, La.; A. R. Kenney, Green Springs, Ohio; O. S. Blakeslee and lady, Sparta, Wis.; Mr. and Mrs. Herman Broeker, Lawrence, Kan.; Mrs. Mallory, Ord, Neb.; Mr. and Mrs. F. A. Gordon, Mr. and Mrs. J. W. Morris of Fairbury, Ill.; J. Loewenberg, Centralia, Ill.; W. C. Forterm, Little Rock, Ark.; Mr. and Mrs. J. F. Bustin, San Angelo, Texas; Wm. F. Stubinger and two friends, St. Louis, Mo.; Miss Eva Simons, Miss Grace Simons, Yonkers, N. Y.; Mrs. Fred. Belden, Kaneville, Ill.; Mrs. Louise Van Northwick, John Van Northwick, Batavia, Ill.; Mrs. W. B. Dodson, Geneva, Ill.; Miss Merrill, Sioux Fall, So. Dak.; Mr. and Mrs. L. B. Sandford, Atwater, Ohio; O. L. Frazier, Davis City, Iowa; Mr. J. C. Freeman, son and daughters, Madison, Wis.; Mr. and Mrs. Jas. A. Ward and sons, Muncie, Ind.; Mrs. C. C. DeCamp, Durand, Mich., and Mrs. C. S. Scott, Moscow, Idaho.

THE BRAND STOVE COMPANY of Milwaukee, Wis., have issued an announcement under recent date, to the effect that Julius Goldschmidt, vice-president of the company, and for the past four years U. S. Consul General at Vienna, has returned to Milwaukee, and again taken up the duties of his office. The company also announce that they have largely increased their producing capacity and storage facilities by the erection of a spacious warehouse. They also have attractive offices and sample rooms where they will be pleased to welcome at all times their friends in the trade and show them the well-known Famous stoves, ranges, heaters, &c.

THE THOMAS ROBERTS, STEVENSON COMPANY of Philadelphia, stove manufacturers, have contracted for the erection of a one-story brick foundry, 100 x 47 feet, and a three story brick storage house, 33 x 66 feet, as an addition to their plant at Second and Mifflin streets.

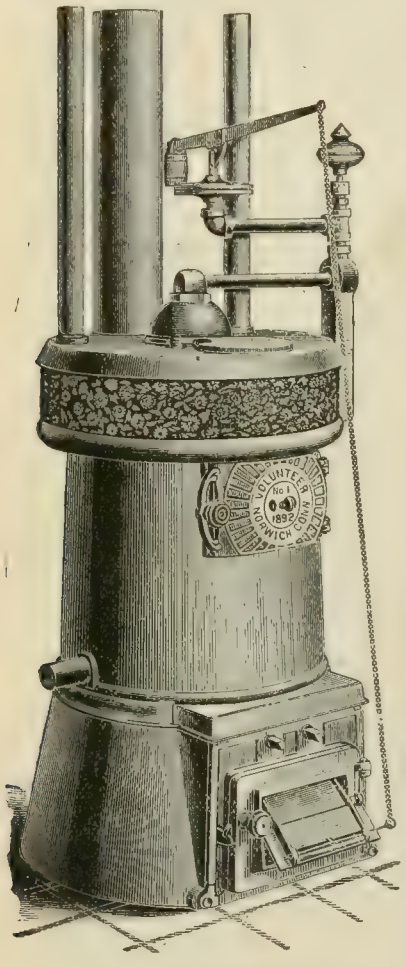
ON AUGUST 1 the firm of Armstrong & Co. of Perryville, Md., was incorporated and made a stock company with a capital of $75,000. The new concern will operate under the name of the Armstrong Stove & Mfg. Company, with William Armstrong president, James Gardner vice-president and F. W. Jones secretary. The directors include the above named officers, together with William H. Cole, Nelson E. Whitaker, J. B. Oldershaw and James W. Strong.

THE NEW PLANT of the Scranton Stove Works of Scranton, Pa., was recently visited by several out-of-town people, among the number being C. E Dunham of Bound Brook, N. J., and F. L. Harrington of Burritt & Co. of Weedsport, N. Y.

STEAM AND HOT WATER.

No. 1 Volunteer Hot-Water Heater.

In the accompanying illustrations we show views of the No. 1 Volunteer Hot-Water Heater lately patented by the



No. 1 Volunteer Hot-Water Heater.—Fig. 1.—General View of Boiler.

William H. Page Boiler Company of Norwich, Conn. Fig. 1 is a general view of the apparatus, showing its peculiar features, it being a very low boiler and neatly decorated at the top. Fig. 2 illustrates separate parts of the heater. The boiler, which is self-regulating and intended for hot-water circulation, is different in form from the other Volunteer hot-water boilers of this firm, the only points in common being the fire pot and ash pit. The boiler has only one section and is designed to set in a back shop, heating that room and also a front or sales room by radiators. It may also be used to heat small cottages of three or four rooms, and is particularly well adapted for heating brooder houses for raising chickens. A convenient feature is a place for heating glue or cooking food for chickens. Referring to Fig. 2, which shows the separate parts of the No. 1 Volunteer heater, on the left is the ash pit and on the right the fire pot, so placed as to show the inside appearance, also the number of nodules or fine points which are cast upon it to prevent the water from chilling the fire. In the center of the cut is shown the under side of the top section. The lower opening through the section is for setting in a kettle, and shows the cover partly swung open. The upper opening is the smoke exit. The center shows the bottom of the regulator tank, the space around it being water space. The next space is for the flue receiving the heat from the fire-pot openings, which passes out directly under the kettle opening and thence around the outer flue to the smoke-pipe exit.

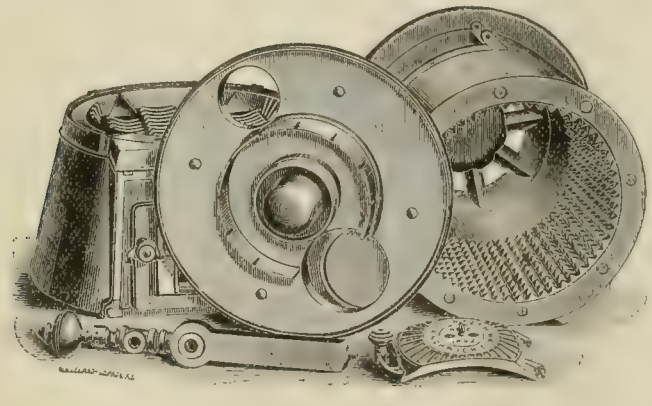


Fig. 2.—View of Separate Parts of Boiler.

A Fine Show of Radiators.

The A. A. Griffing Iron Company, Jersey City, N. J., have made a handsome change at 15 Dey street, their New York office. A fine Brussels carpet covers the floor of the show room, and the walls and ceiling have been freshly frescoed. New offices of attractive finish are arranged at the rear, and electric lights give an illumination only surpassed in brilliancy by Manager Sherman. In the show windows are arranged some of their finest goods. The main sample room is divided from the front by a low railing, at each end of which, at the wall, is a pyramid of electro-bronzed corner radiators at one side and circular radiators at the other, and an umbrella stand made of Bundy sections is on each side of the entrance. In this outer chamber, as attractions, on one side are a stack of Bundy indirect radiators and a new pin indirect radiator; on the other side, in a glass case on the wall, the evolution of the Bundy radiator bronze is shown, from the original bronze bolt beaten in various stages until it is ready to be ground, and glass tubes show the different colors of bronze that can be furnished. Stepping inside the railing the Bundy radiators, arranged with superb effect, are shown in various sizes, colors and styles. When contemplating an exhibit at the World's Fair an investigation showed the company that it was possible to make up 58,000 radiators, no two of which would be exactly alike in every particular. New goods are being prepared, and only those that have made their appearance are mentioned. The Columbia is a new radiator, made for hot water and also for steam, that is of ornate design and susceptible of rich effect in bronze and colors. It is made in all the various hights. The Bundy flue radiator is a stylish new radiator, presenting extended surface and possessing the fashionable flue feature. A new size, 38-inch loop, is added to the Elite line. A duplex damper is a new specialty for use with box base Bundy radiation. Little is left to be desired in elegance by the Bundy Art Tile radiators, which are furnished in a variety of styles, in color and design. The Bundy Renaissance high art radiator presents beauty worthy of any surroundings. A handsome piece of sheet brass work received from a customer enables a Russian bath to be enjoyed by connecting a rubber tube with the air cock on a steam radiator and with the brass chamber, which is perforated to permit the steam to escape in fine jets to moisten the air.

The Lunken Gate Valve.

E. H. Lunken of the Lunkenheimer Company, Cincinnati, Ohio, has invented a new gate valve which is very ingenious and simple, and embraces a number of features. Its compactness is indicated by the fact that a 1-inch valve to carry 150 pounds working pressure weighs ¾ pounds less than the lightest common globe valve. The hub or bonnet is held to the shell by a coppered steel clip or strap surrounding the shell, with its ends passing through the ears of the bonnet and secured by nuts, O, Fig. 1. This clip is held from lateral movement by projections on the shell. The joint is packed by a hard lead washer $\frac{1}{64}$ inch thickness, the top faces of flanges each having a groove to properly secure the washer. The valve can easily be taken apart without renewing the packing washer. The hub or bonnet is flat and narrow and just of sufficient size to receive within it the valve disk when entirely raised, and has sectional or part-nut threads in its opposite interior sides. The threaded portion, J, Fig. 2, of the stem, by engaging with these part threads, causes the valve to be opened or closed. The disk has a straight flat face or bearing against the renewable seat C, Figs. 1 and 2, and is forced tightly against same by the self-adjusting wedging half ring or horseshoe D, Fig. 2, secured loosely in

the valve shell. The wedging on the disk is applied on two wedging surfaces diametrically opposite each other, these coming in contact with the beveled ends of the half ring or horseshoe wedge; thus the wedging pressure is equalized on the entire disk and insures a tight joint on the opposite face. The pressure of the steam or liquid on the back or wedge side of disk also aids to make a tight closing valve.

All valves above 2½-inch size are provided with "by pass," which arrangement balances the disk before opening, and thus reduces the friction and wear on seat and disk and makes the valve open easily. The "by-pass" is shown in Fig. 3. It is an auxiliary valve formed in the top of the valve disk (immediately below the yoke that secures same to the flanged head of the stem H, Figs. 1 and 2) and is operated by the stem of valve, automatically, while opening or closing the main valve C. its threads into the threads in the shell. With the aid of the wrench the cheap seat is very quickly renewed. Another important feature is that the stem, when valve is full open, seats itself, V against U, Fig. 2, thus relieving all pressure on the stuffing box and permitting repacking of same under pressure. The tie band surrounding the shell adds to the strength of the valve and permits of its being taken apart easily with a small wrench. The shell is so short and rigid and the wedging surfaces are so small that expansion and contraction little affect it. Thus the disk will not wedge fast. Having but a single disk and the wedging half ring taking the place of a second disk as a wedging resistance, this construction, it is pointed out, overcomes the objection in double disk gate valves where liquids remain in the shell between the disks and often freeze or injure the valve. Nothing can lodge on the tubes, reaching from the bottom of the lower chamber to the top of the upper chamber, materially increase the heating surface. The outside pipes radiate directly and the inside heat the air rising from the floor. A little pamphlet is likewise issued, giving ten reasons why this radiator is superior to others.

SEALED PROPOSALS will be received at the office of the Supervising Architect, Washington, D. C., until August 30, for all the labor and materials required to put in place, complete, a heating and ventilating apparatus in the United States Post Office Building, Sacramento, Cal., in accordance with the drawings and specification, copies of which may be had at the office of the Supervising Architect at Washington, or from the superintendent at Sacramento.

THE ST. LOUIS MFG. COMPANY, St. Louis, Mo., issue an illustrated and de-

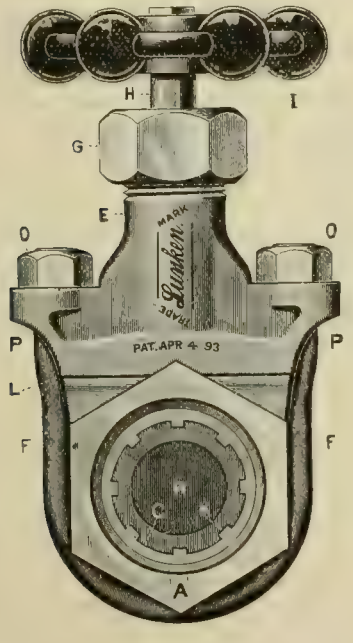

Fig 1.—End Elevation.

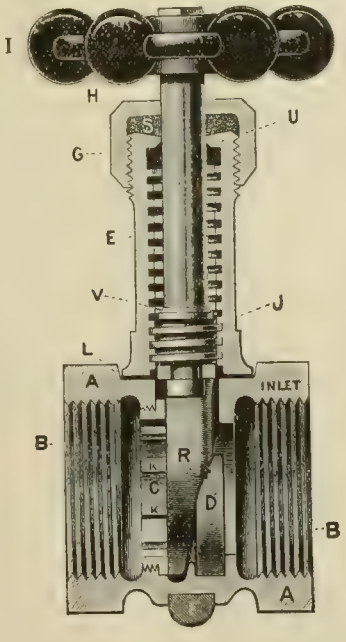

Fig. 2.—Longitudinal Section.

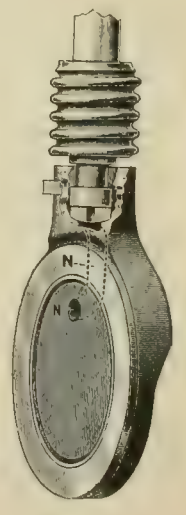

Fig. 3.—The By-Pass Valve.

THE LUNKEN GATE VALVE.

Channel N, Fig. 3, passing through the disk, connects the inlet or pressure side of the valve with the outlet side, and the end of the stem H controls this channel, there being sufficient play in the disk coupling to allow the complete opening of channel N caused by the first one-sixth turn of the wheel in opening the valve.

The renewable seat is an exteriorly threaded flanged ring that screws against a face or shoulder of the flange, the opposite side of which flange forms the seat or bearing surface for the disk to close against. The inner periphery of the renewable seat has lugs or teeth, K, Fig. 1, for the engagement of the spanner end of a wrench, by which means, after taking off the bonnet E, Figs. 1 and 2, the seat is tightened or loosened through the disk opening of the body without disturbing the pipe connections. In iron body valves the renewable seat C screws into a second brass ring, permanently fastened in the iron shell, otherwise, owing to the rusting qualities of iron, the removable seat might rust tight in the shell.

The wrench has a ring end which is used to hold and guide the removable seat into place, so as to properly start seat of the valve, because the disk and seat have a parallel straight face, and as the pressure on the back of the disk keeps it tightly pressed against its seat it cuts away anything in its path. This feature, combined with the renewable seat, commends this valve for blow-off purposes. As regards outside finish, the shape and construction are such that necessitate only the finishing of the stuffing box, the balance being left a smooth casting, while the steel band and nuts are drop forged and copper plated to prevent rust.

HEATING NOTES.

THE MILLS SYSTEM OF HOT WATER HEATING is described in a circular issued by W. B. Mills of Deckertown, N. J. The radiators used in this system are said to be of peculiar construction, and on this construction the success of the method depends. They consist of upper and lower chambers connected by upright pipes, each of the pipes being double, one within the other, leaving a small water space between them. The outer pipes are connected to the top of the lower chamber and to the bottom of the upper chamber, while the inner

scriptive circular relating to what they describe as their new radiator named the Holland. Special attention is directed to the connections used. The right and left hand stud bolts permit disconnection in a minute, if a leak is discovered. This, furthermore, can be done without removing the valve connection, and so avoids the necessity and expense of ending the radiator up to be swung off loop by loop. There are no nipples or screwed ends to come in contact with the steam or hot water to become rusted. The opposite faces of the loops are made male and female and a Jenkins' gasket put between them, the faces being brought together by right and left hand stud bolts located in an accessible place. These radiators, which are made for either steam or hot-water heating, are put up in from 2 to 32 loops and in five sizes, from 20 to 45 inches in hight. The 2-loop radiator is 5 inches in length, and built of the 32 inch section, contains 6⅜ square feet of heating surface. The loop is 7¼ inches and the width across the feet 9¼.

THE LUNKENHEIMER COMPANY, Cincinnati, Ohio, issue a cordial invitation to their friends and patrons when visit-

ing Chicago to see their exhibit installed in Machinery Hall, section 25, Column O 24, where they have a complete line of the Lunkenheimer specialties in charge of one of their representatives, who will take pleasure in showing and explaining the merits of their various productions. This greeting comes on a prettily printed double page circular issued by the company, and in addition to the text there is a neatly engraved view of Machinery Hall.

THE MACKAY MFG. COMPANY, 66 James street, Newark, N. J., are a recently organized concern for the manufacture of a number of specialties which are the invention of W. M. Mackay. Among the goods that the new firm are manufacturing and selling are the Mackay patent quick operating hot-water radiator valve and the Mackay mercury thermometer for hot-water heaters. Other goods are Union elbows, wrench plugs and lock shield air valves.

SEALED PROPOSALS will be received at the office of the Supervising Architect, Washington, D. C., until August 11, for the heating apparatus for the extension of the United States Custom House Building at Chicago. Drawings and specifications can be obtained at the office of the Supervising Architect, or the office of the superintendent at Chicago.

THE WALWORTH MFG. COMPANY, Boston, Mass., are now well settled in their New York office, having moved to 56 Beekman street, where the manager, E. P. Keane, has a fine line of samples of their specialties for steam, water and gas. A 12-inch Walworth gate valve, attractively painted, is fixed at one side of the entrance on the street to show the passing steam fitter that he need go no farther for pipe tools, fittings, valves and the Walworth goods.

"THE FAULTLESS FURMAN HOT-WATER AND STEAM BOILER" is the title of a handsome publication issued by the Herendeen Mfg. Company, Geneva, N. Y. The volume is a bulky one, containing over 200 pages, and begins with some interesting observations on the general subjects of steam and hot-water heating, incorporated in which is a thorough description of the Furman heater. Forty pages are given up to this matter; then comes a notice of awards to the Furman boilers, followed by tables of sizes and prices. The next division consists of testimonial letters, sprinkled among which are many engravings of the houses where the Furman heaters are installed. This part of the book covers nearly 170 pages. This, in turn, is followed by a long list of references of those who used the boilers. Accompanying this volume is a smaller treatise, being the second edition of "Home Warming and Ventilation," a collection of articles by various authorities. An invitation from this firm to those visiting the World's Fair is that they will be glad to have them call at their Chicago office, at 79 Dearborn street.

SEALED PROPOSALS will be received at the office of the Supervising Architect, Washington, D. C., for all the labor and material required to furnish and erect a new low pressure return circulation steam heating apparatus, including power boiler and all pipe connections and non-conducting material, for the Butler Building, Washington, D. C., in accordance with drawings and specifications, copies of which may be had at the office of the Supervising Architect.

A Notable Key.

At the recent inauguration of the Imperial Institute in London, the key which was presented to Queen Victoria, wherewith to perform the opening ceremony, was in its form and composition entirely unique, and well worthy of mention. The gold, silver and jewels of which it is made were contributed by the several Colonial governments under the British Crown, and by India, so that the different portions of the empire are represented by its various component parts. The head of the key is formed of gold from South Africa, the silver in the star ornaments of the handle comes from the Broken Hill Mine, Australia; the stem is formed of gold from British Columbia, while the bitt and wards are composed of the precious metal from Queensland mines. The stem of the key is enriched by a rib-band in red gold and a wreath of laurel leaves in green gold, both obtained from Victoria. The key and ornaments are set with diamonds from South Africa, rubies from Burmah, and pearls from Ceylon. The object is of beautiful and rich design, the head being circular, with the royal and imperial crown on the summit, and the Maltese cross with *fleurs-de lis* forming the outer border. The center of the key head displays on one side the jeweled star of the Colonial Order of St. Michael and St. George, and that of India on the reverse side. The national emblems —the rose, shamrock and thistle—surround the arms of Great Britain at the top of the stem. The stem and wards are decorated in accordance with the rest of the key, the wards forming the initials, I. I., of the institute. The key was the work of Chubb & Sons of London.

The following details are given by a Mexican journal of the tin deposits recently discovered near Guyanjuato, Mexico, by Frank Gordon, an American prospector: "Eight leagues from Silao and 14 from Guyanjuato there exists deposits of the class of tin known as 'kidney.' It is found scattered all over the district. The inhabitants collect it, smelt it in a furnace of primitive construction and sell it in the market at $29 per quintal. The veins in which the tin exists are still in a condition of primitive formation, and are what is known as 'vetas apartadas.' The tin in its metallic condition contains a good deal of gold, and for this reason obtains a ready sale. The average yield of ore is 50 per cent. of metallic tin. The beds from which the tin is extracted are covered with compressed sand, mixed with rubble and resembling concrete. Samples of 'kidney' tin have been taken out in this district weighing 5 pounds. Near the land where it is found exists sundry auriferous veins and large carboniferous croppings."

In a recent communication to the Paris Académie des Sciences M. Henri Moissan claims to have succeeded in forming diamond dust artificially. The plan adopted was to inclose some purified carbon in a wrought-iron receptacle, which receptacle was tightly closed by a screwed plug. Iron was then melted by the electric arc, and when quite fluid the iron bottle containing the carbon was placed in the molten mass. Afterward the crucible is rapidly cooled with water, forming a hard skin of solid metal round a still liquid interior. This fluid portion, solidifying later, endeavors to expand, as usual, and the consequence is it is subjected to a very high pressure from the unyielding wall of previously cooled metal. When quite cold the residue obtained on dissolving away the iron with hydrochloric acid is found to contain several varieties of carbon, among them being very dense and very hard particles, many of which are quite transparent, while others resemble carborads. These particles scratch the ruby, and have a specific gravity of 3.5. When heated to 1000° C. in a stream of oxygen gas they completely disappear.

The smokeless powder adopted by the English Government is known as cordite. It derives its name from its structure, the powder being made up of strings or cords of varying thickness, from $\frac{3}{1000}$ inch to $\frac{1}{3}$ inch in diameter. The thick cordite is cut in long strips of 14 inches. The cordite used in field guns is cut in strips measuring 11 inches in length. The small-arm ammunition is made up of 60 strands to a load. According to Colonel F. W. Burke of the British artillery the new cordite is a combination of nitro-cellulose and nitro-glycerine. The combination is 37 per cent. gun cotton, 58 per cent. nitro-glycerine, and 5 per cent. vaseline, to which is added a proportion of acetone distilled from wood. The mixture takes on a stringy form. In a magazine rifle a charge of 70 grains of black gunpowder gives a velocity of 1830 feet a second, while 30 grains of cordite gives the same bullet a velocity of 2000 feet.

The manufacture of thermometers, barometers, and kindred instruments, is an industry which is a comparatively recent one in the United States. But a few years ago most of these instruments were imported from Germany, or other parts of Europe. Now, however, American firms are turning out thermometers and barometers which are equal and in some respects superior to any made in the old world. The American "Standard" barometer, for example, is considered the best in existence; while thermometers of all kinds are turned out from American factories which will compare favorably with any of foreign make. In the manufacture of special instruments—as lactometers, urinometers, acidometers, pyrometers, &c.—the trade is so far held by foreigners, but it is stated to be only a question of time when these and other articles in the same line will be made in the United States so cheaply as to enable American manufacturers to export considerable quantities besides supplying the home market.

Wire glass for architectural purposes appears to be now manufactured in Germany. A contemporary states that material of this description, made in Dresden, was recently tested at Berlin in order to try its fire-resisting qualities. Plates of wire glass are said to have been placed in three different situations, as roof lights and walls, in the testing structure, and, after being exposed to high heat, showed no damage beyond a few unimportant cracks. The fact was, however, ascertained that sheets of this glass, to be properly employed in fireproof construction, must be securely fastened to the iron frame work in order to prevent their falling out whole when the iron is softened by the heat. We learn that the material has been awarded a prize by the Government commissioners in charge of the tests.

TIN PLATES.

Tin Plates and the Tariff.

It can be announced with the utmost confidence, writes our Washington correspondent, that it is the determination of Secretary Carlisle, as far as his department is concerned, among the other recommendations in the direction of a long list of articles to be put on the free list, to add the repeal of the provisional $2\frac{2}{10}$ cents tin-plate duty.

The grounds for this announcement is the fact that the Treasury officials, who are tinkering with Special Agent Ayers' report on the production of tin-plate in the United States under the statute, have for some weeks been making a very searching examination of the proceedings during the protracted discussion of the tariff in the Fifty-first Congress. They wish to find some justification for such a course in the general tone of the debates and the admissions and alleged contradiction of facts and figures in sustaining the imposition of the specific duty, and the provisional legislation leading to free tin-plate if the development of the home manufacturer did not come up to a certain relation to importation of foreign tin in a given time.

In event of failure to find sufficient grounds to satisfy their official consciences in favor of absolute and immediate repeal, the Treasury officials have also been examining the debates on the provisional portion of the tin-plate legislation in order to ascertain whether in the tinning of imported black sheets the product was to be considered as American tin plate and to be included in the statistics of American production. The department has not confined its inquiries to the home sources of information, but has instituted inquiries into the interpretation of these conditions in Wales. They wish to find out whether English black sheets tinned in Wales are embraced under the head of tin plate manufactured in Wales, or whether the tinning does not cover the black sheets to the extent of making them Welsh tin plates. The department is making determined efforts to get tin plate on the free list, if not by recommending what would be nothing short of a breach of faith by Congress with the American manufacturers—that is, immediate repeal—then by making it appear that the aggregate quantity of tin plate lighter than 63 pounds per 100 square feet produced in the United States during either of the six years next preceding June 30, 1897, has not equaled one-third the amount of such plates imported and entered for consumption during any fiscal year after the passage of the act and prior to the above date.

The exclusion of foreign plates tinned in the United States from the statistics of the home product of tinned plate would make a serious difference, as may be seen from the product of 1891–2 fiscal year, July to June, when the relation stood:

	Pounds.
Amount of tin plates made from American black plates	9,300,000
From foreign black plates	4,300,000

These figures were more unfavorable from the department standpoint in the last two quarters of the calendar year of 1892, viz.:

From July 1 to December 31, 1892.

	Pounds.
Tin plates from American black plates	14,000,000
Tin plates from foreign black plates	17,000,000

There is a fixed determination to attempt some very radical so-called revision or reform of the metal schedule under the tariff act of 1890.

SCRAP.

THE COST of a tin-plate manufacturing plant in the South Wales district is estimated at $14,400 per mill, including all the necessary appliances.

JAMES B. SCOTT & Co., Pittsburgh, Pa., issue a colored circular directing attention to Scott's 'Extra Coated Guaranteed American Roofing Tin. They say that they have had two years' experience in manufacturing this brand in their factory in Pittsburgh, and have spared neither time, pains nor expense in its production. Describing this plate, they speak of it as made of superior quality American soft steel, each sheet accurately resquared, coated with the best refined block tin and lead, and only strictly prime Lagos palm oil being used.

THE TIN-PLATE WORKS of Somers Bros., Brooklyn, have been shut down temporarily.

THE LEECHBURG FOUNDRY & MACHINE COMPANY recently shipped to the Cumberland Steel & Tin Plate Company, at Cumberland, Md., a 20-inch tin mill, and a 36-inch doubling shear with engine attached, and one Mesta patent automatic pickling machine. The addition of this equipment will allow the latter named concern to more than double their present output.

THE STORE of tin in the mines of the Straits is said to be practically inexhaustible. A recent report from that district says that, in the opinion of practical men, these mines have been only superficially prospected so far. As more than half the tin supply of the world is obtained from the Straits, scarcity of the metal need not then be feared. The output of the mines has steadily increased of late years, and the increase is likely to continue. The following figures show the exports in tons:

1887	27,549
1888	29,169
1889	33,021
1890	31,976
1891	36,061

For the years 1890 and 1891 the principal shipments from the Straits, by countries, were as follows, the picul being $133\frac{1}{3}$ pounds:

	1890. Piculs.	1891. Piculs.
United Kingdom	267,238	293,024
Austria	5,295	4,035
France	40,935	45,446
Germany	2,102	2,532
Holland	14,304	18,355
Italy	3,698	6,676
United States	118,243	163,647

These figures show a marked increase in the shipments to the United States, which may be attributed to the establishment of the tin-plate industry in this country during the latter half of 1891.

A Knotty Point of Equity.

How controversial we are as a people and how prone some of us are to carry a point to an extreme, writes "Vulcan," in the London *Ironmonger*. This was well illustrated recently. Early one morning an assistant in a hardware store put some bread platters in his window, each one being ticketed with its price. Later on, to improve the display, he laid some knives on the platters, and then, feeling satisfied with the result, went on with other work. But before many hours had passed a knotty problem presented itself. A customer came and claimed a platter and knife at the price of the platter alone. When the claim was resisted he said some very hard things. It was explained to him that the platters and tickets were put in first and the knives added afterward as an afterthought. This explanation would have satisfied most people, but it was useless in this case. The customer stoutly protested that legally he could demand the goods and he was determined not to forego his legal rights.

Here was an opportunity for controversy much too tempting for two Englishmen to miss. The buyer's claim was this—the knife lay on the platter, "and therefore," said he, "the ticket on the platter referred to both articles." The seller resisted this on the ground that there was nothing on the ticket to indicate that it referred to more than the single article on which it rested. The dispute was carried on with spirit, and might have lasted all day but for the intervention of the principal, who, while showing the buyer the unreasonableness of his claim, freely admitted that the tickets were ambiguous, and then offered to adopt the buyer's own interpretation and let him have the knife free. It was truly comical to see the change this effected. At first the buyer wanted, by means of a quibble, to get more than his due; now he refused to have the goods at other than full price. It was delightfu to see the seller urging him to take the knife for nothing, and the buyer begging to be allowed to pay for it. At length a settlement was arrived at, and the whilom opponents parted on the best of terms. Tact is sometimes more useful than talent.

As illustrating the curiosities of trade and manufacturing economy, an English contemporary states that thin sheet iron is being sent from South Staffordshire into Germany, where it is worked up into wrought hollow ware and other kindred goods and sent back to England, where it meets with a ready sale, underselling in price English pro ductions of the same description.

THE RETAIL STORE.

The Profit of the Hardware Business.

BY WM. H. MAHER.

In these days there is no branch of business in which competition is not sharp and aggressive, but in some lines of trade it is much more severe than in others.

For instance, the average man supposes because he is a consumer of groceries that no special experience is required in buying and selling groceries over a counter. Hence men start in that business without experience and with little capital. How little is evidenced by an incident coming to my knowledge within a few days, where application was made by a man and his wife for credit for a stock of groceries. It developed that they had $50 in cash and no experience in business, but considered themselves well equipped for starting a small grocery. They were advised to wait awhile until their capital was larger, but the chances are that they found a salesman who proposed to have that $50 and the trade of this pair of merchants.

Every man believes that he can weigh out and do up sugar, draw molasses and vinegar as well as any other man. The consequence is that men start a grocery and cut prices to draw trade, fail, and are succeeded by other ambitious and equally ignorant men.

The dry goods trade is constantly recruited from its own ranks, usually from men who have been heads of departments. They have been permitted to buy their own goods, and, to a very large extent, have also had influence in making prices at which the goods shall sell, and are firmly convinced that they know the dry-goods business from A to Z.

The general expenses of running a store are a mystery to them. The acquaintances they have made in the way of business they look upon as personal, and their trade a tribute to their own popularity. They impress their acquaintances with their supposed popularity and ability, and induce their friends to help them into a store of their own.

Finding that the people who formerly traded at their counter do not follow them, they are obliged to offer inducements by cutting prices, and there is so much of this that the dry goods business of the country has become one of small profits, and to be successful must be backed by ample capital and command large sales.

The drug business is one that demands long apprenticeship, if the owner of the store would be independent of his clerks. The druggist must be a chemist to make his prescription business profitable, yet his worst competition is from druggists who are without experience, and who depend upon clerks for all the technical knowledge needed in the business.

Aside from this, what was formerly the most profitable part of the drug business, patent medicines and proprietary articles, are to-day made leaders and baits in department stores, and they will probably continue to be so used, for extensive advertising creates a demand for them, and the regular prices are so well known that a cut price is at once understood by the public.

The Hardware business is not one that attracts the majority of young men. It is not of itself a stepping stone into "society." It offers no inducements to the dudish young man who thinks more of his clothes than of his brains. It does not attract the superficial man who is more exercised about the wages he receives to-day than the position he will have a few years from this.

Competition in the Hardware trade is rather one of brains and ability than one where men simply expect success by underselling each other.

There is no special rush of men into the Hardware trade in any given locality. When a man who has been a Hardware clerk prepares to start in business for himself, he has learned that capital is necessary and that business is not created in a day.

The young man who is about to select a business should consider his own tastes and adaptability, the position any given trade occupies as a money-maker, and the means it offers of gaining the acquaintance and good-will of his fellow men.

He will see that a very large percentage of the customers of a dry goods merchant or grocer is composed of women and children. The hardwareman deals as largely with men. His principal trade is with farmers, builders, mechanics and manufacturers. These are the men who make a village or city. These are the men whose personal acquaintance is of value in business and helpful in social and political life.

When one compares the stable character of a stock of Hardware with the unending changes of fashion in a dry goods store, or the great loss from perishable goods in the grocery store, the business commends itself because of this. Ninety-five per cent. of the stock in a Hardware store is as salable to-day as it was a year ago, and will be just as merchantable a year hence.

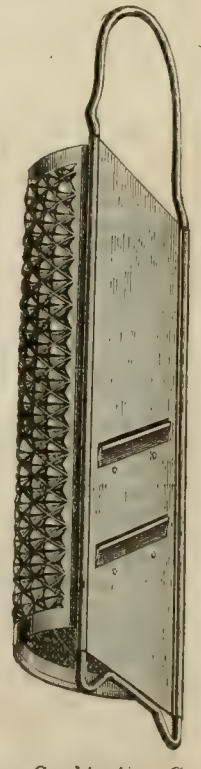
The expenses of running a Hardware store are, proportionately to the business done, much less than in other lines. The store needs not to be located on a principal street, clerks are not required to wait upon shoppers, for a Hardware store does not tempt that class; and customers, being mostly men, generally carry their purchases away with them.

The Hardware business is pre-eminently a business for men. It is a manual training school for an intelligent boy or young man. The salesman who would be successful in selling Tools and Machines must know how, when and where they are used. He must be able to take apart and assemble any machine, tool or weapon that he sells and educate purchasers to do this. This will be conceded by any one who has knowledge of the business, and, being conceded, it is one very strong reason why the Hardware trade is not sought by the mass of men who are looking after easy places.

To the young man who is seeking a field that will pay him best in money profits, as well as bring him into intercourse with the best men in his community, it can be said, with the confidence born of both observation and experience, that the Hardware business offers the most hopeful outlook and the greatest measure of success.

The Spery Combination Grater and Slicer.

Chicago Hardware Specialty Company, 149 Lake street, Chicago, are introducing the above article, as herewith



The Spery Combination Grater and Slicer.

shown. The article is made of the usual sheet grater, having, however, a galvanized-iron back, in which are inserted two steel knives for slicing. The blades can be taken out for cleaning, or to be used separately. The manufacturers state that the article is strong and durable and that its combination is desirable.

Arrangement of Stores.

Weed & Co., Buffalo, N. Y., are proprietors of the "Old Hardware Store," established in 1818, to which the accompanying illustrations relate. Although the business is old in years, the store is modern in arrangement, as the fact is recognized that well-displayed goods are more easily sold, and that the lines bearing the best profit are the ones to push to the front. The store is a double one, having shelving on each side of the partition and also against each side wall, the two rooms being connected by passageways, one of which is shown in Fig. 1. This represents the front of the middle or partition shelving, the opening in front extending to the store front.

The shelving extends to the ceiling, and is filled with sampled wooden boxes to a considerable hight. Above these stock is kept in original packages, the whole being reached by a traveling ladder. This shelving is devoted to Tape Measures and Carpenters' and Mechanics' Tools. The boxes are finished in natural wood, each with a drawer pull; and in addition to the samples, in the case of Tapes, the kind and length are stenciled on each box.

A showcase devoted to Pocket Cutlery runs around the front of the partition, and the shelving is arranged in the same manner on the other side. The goods sampled here are Cork Screws, Drawer Pulls, Conductors' Punches, Jack Chain, House Numbers, Ice Picks, Wire Picture Cord, Screw Hooks and Eyes, Butts, Casters, Match Safes, Lemon Squeezers and miscellaneous goods of this character. On the end of the partition Thermometers, Bird Cage Hooks, Key Chains, Bird Cages, &c., are sampled. Counters and showcases are in front of the shelving on each side of the partition.

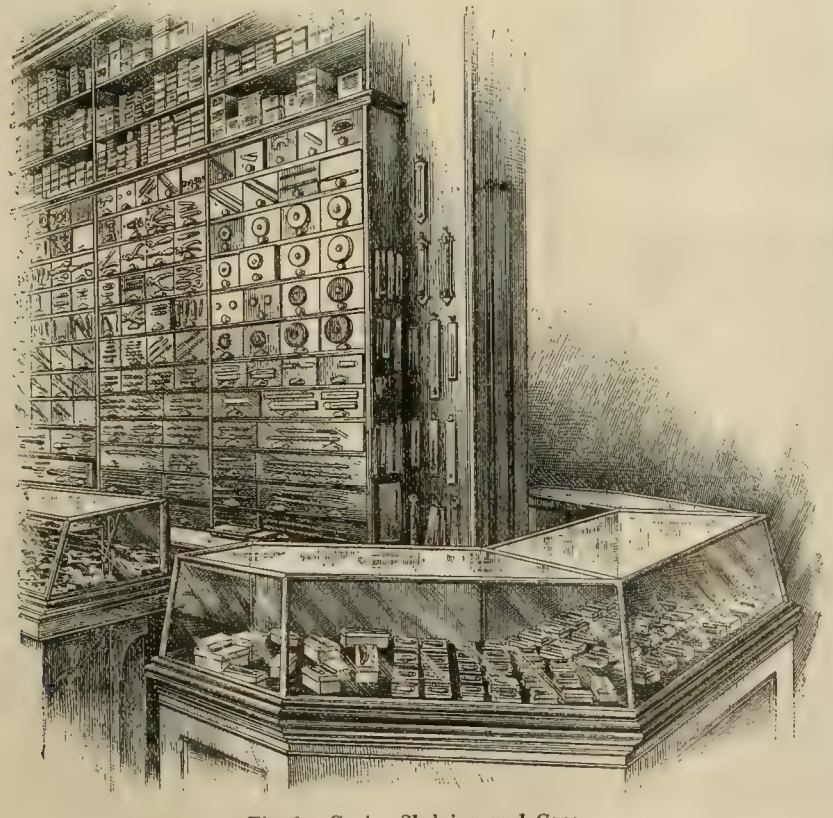


Fig. 1.—Center Shelving and Case.

On the side of the store opposite the shelving in Fig. 1, is a wall case extending back about half the depth of the store. A portion of this case is shown in Fig. 2. This is devoted to Hand, Meat and Back Saws, Hammers, Hatchets, Planes, Plumbs and Levels, &c. The showcase immediately in front of it contains smaller Planes and fine Tools. Duplicate stock of Saws is kept in the original boxes underneath the case.

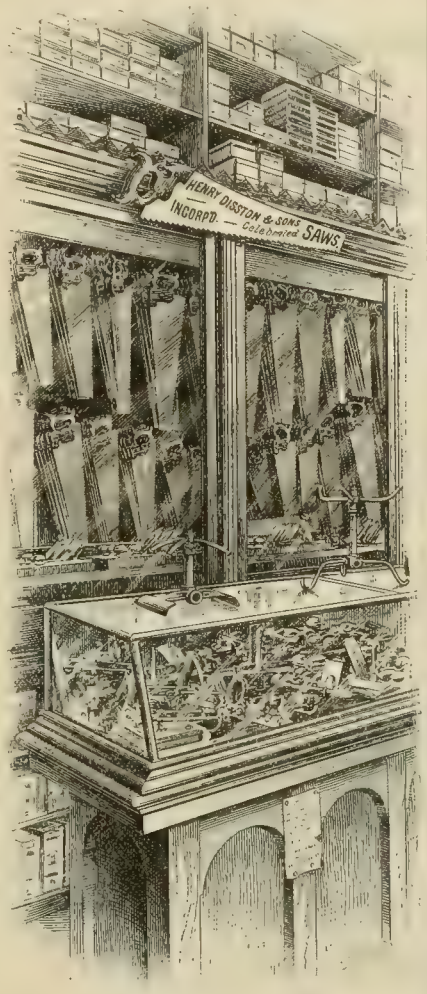

Fig. 2.—Saw Case and Tools.

The arrangement of Carvers is shown in Fig. 3, the case being against the wall in the other part of the store. This method of arrangement allows of four lines of shelving, two in each room, with a corresponding number of counters. The shelving all extends to the ceiling, and each line is provided with a traveling ladder. A system of cash carriers is also provided for each line of shelving.

The glass doors in front of the Saw and Cutlery cases are hung on weights, and push up out of the way. The boards on which the Carvers, Steels, &c., are sampled slant from the front at the bottom of the case, to the back at the top. The showcase in front contains Silver-Plated Knives, Forks and Spoons; with samples of Fancy Handled Table Knives against the back, held in an upright position by a band attached to the back of the case.

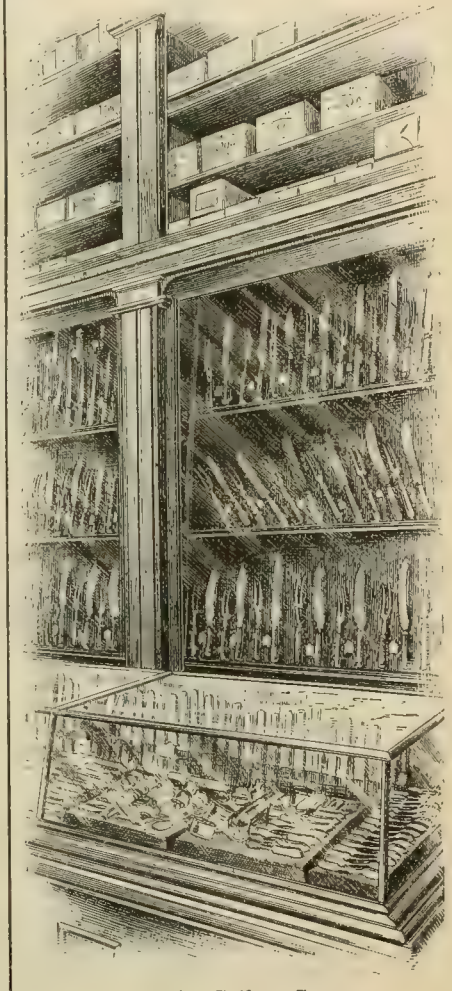

Fig. 3.—Cutlery Cases.

A handsomely fitted up room in another part of the store is devoted to samples of builders' fine Hardware. Drawers or slides with fronts but no sides, finished in natural wood, contain samples of long Escutcheons and Knobs, Butts, Bell Pushes, &c.; while on the ledge over the drawers stand mounted Locks and Knobs. If the line of goods on any particular drawer is to be shown, the drawer is taken out and stood up against the ledge, the bottom resting on a lower slide drawn partly out for that purpose. On the opposite side of the room is a wide counter.

The arrangement for each line of goods throughout the stock has received the same care and attention as those already referred to.

The Monroe System of Refrigeration.

The Monroe Refrigerator Company, Lockland, Ohio, the West & Tice Company, 139–141 West Fourth street, Cincinnati, agents, are introducing a system of refrigeration in their No. 5 refrigerators, as shown in the accompanying cuts. Fig. 1 shows the interior construction of the refrigerator, while Figs. 2, 3 and 4 represent cross sections of the apartments, the numbers of the cuts indicating the position the apartments occupy in the refrigerator. The top apartment is provided with ice rests upon which the ice is placed. The system of refrigeration is explained as follows: The air becoming chilled and heavy passes down the air flue D, as indicated by the arrows in Fig. 1, and into the provision compartments of the refrigerator, forcing the warmer air upward through the air spaces 1, 1^1, 1^2, 1^3, 1^4 and 1^5 in front and behind the provision compartments in Figs. 3 and 4, to the return flues 1^6, 1^7, 1^8 and 1^9 in Fig. 2; through which it continues to the top of the ice apartment, as indicated by the arrows at the top of Fig. 1, to the ice where it is chilled and passes down through the flue D, thus keeping a continuous circulation so long as there is ice in the refrigerator, causing the entire atmosphere within the refrigerator to pass over the ice every few minutes. It is stated that all vapors and minute particles given off by the food are thus carried to the ice where the vapors are condensed and the minute particles deposited and carried off by the drippings which pass down the sides of the flue D, and out of the refrigerator through the drip pipe and trap O. The point is made that as all vapors are condensed on the ice the provision compartments are free from sweating and that matches could be kept in them in perfect condition for any length of time; also that the water from the ice, in passing down the walls of the air flue, assists in cooling the refrigerator, thus utilizing every particle of ice. The trap at the bottom of the refrigerator is to form a water seal to prevent air or heat from entering through the drip pipe. The manufacturers claim that the movement of the air in the provision compartments being only from the bottom of the refrigerator upward, there will never be any mixture of flavors or tastes if all food likely to give off odors is placed in the top compartments, as the air from these compartments passes over the ice and is purified before it again enters the other compartments; also that by the air being conducted directly from the ice to the lowest parts of the refrigerator before it enters the provision compartments, a low temperature is secured at the greatest distance from the ice, hence the lowest possible temperature throughout the refrigerator.

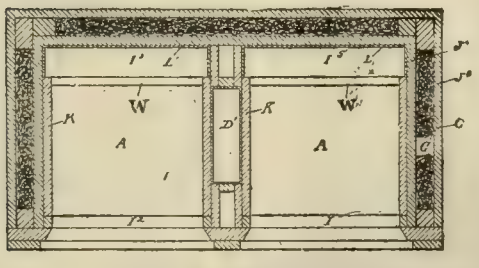

Fig. 3.—Apartment Under Ice Chamber.

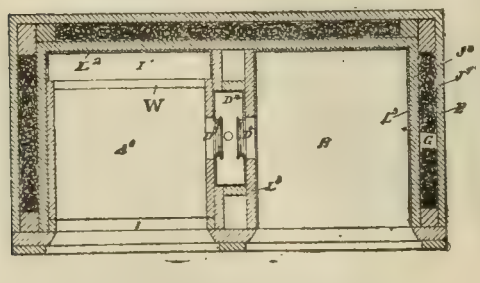

Fig. 4.—Bottom Apartment.

THE BUSINESS OF THE AVERY STAMPING COMPANY, Cleveland, Ohio, was placed in the hands of a receiver Wednesday, July 26. Application for the appointment of a receiver was made by the Junction Iron Company of Steubenville, and Douglas Perkins was unanimously requested to be appointed receiver. The assets of the company are placed at upward of $400,000 and the liabilities at $300,000. The officers of the company are Ralph A. Harman, president; Douglas Perkins, vice-president; Joseph Perkins, secretary and treasurer, and Henry W. Avery, manager. President Harman in an interview said that in ordinary times the company have had no trouble, that on July 1 their balance sheet showed assets amounting to $505,000 and liabilities $296,000 and their business was prospering until it became difficult to obtain ready money. Upon consultation with the Junction Iron Company they decided to take action toward keeping the business in their own hands rather than assign it absolutely to another. President Harman said that he hoped that matters would be adjusted so that operations would be resumed about the middle of August.

Tongs for Handling Ice, Small Fruits, &c.

The Unique Mfg. Company, 35 Murray street, New York, are marketing a novelty, as illustrated in Figs. 1 and 2.

Fig. 1.—Sugar or Fruit Tongs.—Half-Size Cut.

Fig. 1 represents the article, which is offered as an improved medium for daintily serving loaf sugar, bon-bons,

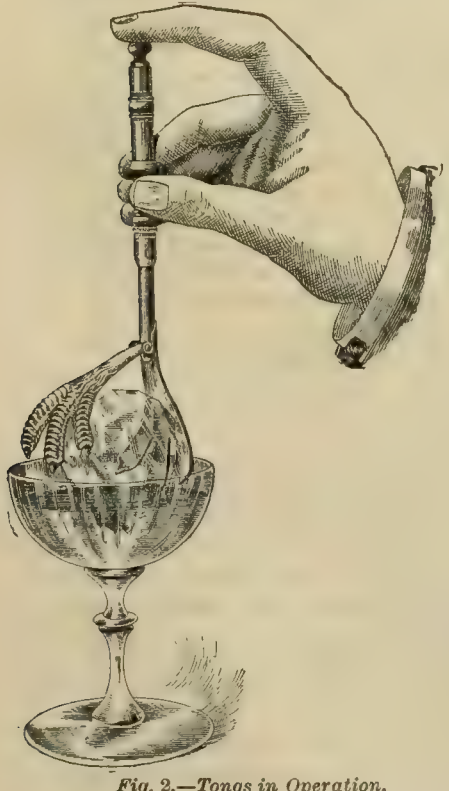

Fig. 2.—Tongs in Operation.

cracked ice, mixed pickles, olives, &c. especially if necessary to extract them from a bottle, or small fruits of any kind. Fig. 2 shows how the tongs are operated. The projecting ring on the handle serves as a purchase, permitting the knob at the top to be pressed, forcing the hinged claw open while the other remains rigid. By means of a spring in the tube, when the pressure is released the object is caught and removed. The goods are 6¼ inches long, plated, and packed in individual boxes.

Improved American Waffle Iron.

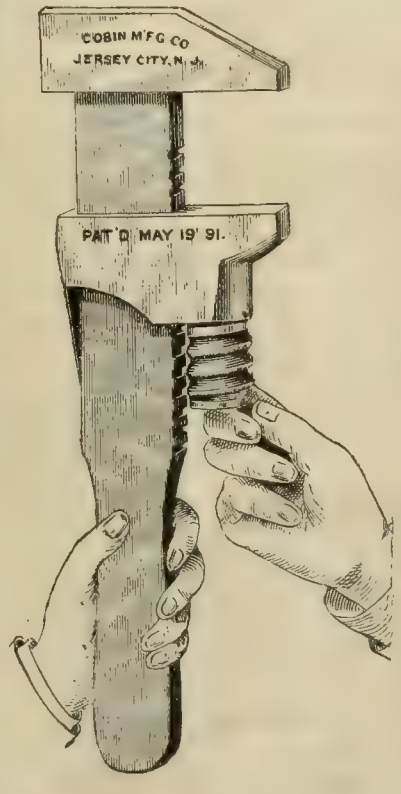
The accompanying illustration shows what is described as the new improved American waffle iron, put on the market by the Griswold Mfg. Company of Erie, Pa., the well-known manufacturers of the Erie hollow ware. This waffle iron is described as very simple in

Improved American Waffle Iron.

construction and can be used on gas or gasoline stoves. A special feature, as shown in the cut, is that the pans can be taken apart to clean. Another point that will be appreciated is the long wood handles, which prevent all danger of burning the fingers.

Adjustable Wrench.

Cobin Mfg. Company, 107 Chambers street, New York, have brought out a



Adjustable Bicycle Wrench.

wrench, as here shown, which, at present, is being made in the 5-inch size for bicycle and similar purposes, but which later they expect to furnish in all the regular sizes to 15-inch inclusive. The principal feature to which the company call attention is the ease and rapidity with which the movable jaw can be adjusted to any size within its capacity. A flat steel spring, riveted to the back of the movable jaw, permits the screw to be pulled out, so as to release it from the grooves in the bar, while a close adjustment is effected by turning the screw to right or left. It can be used either as a ratchet or screw wrench. We are advised the bar is drop forged from bar steel and case hardened. The wrenches are made both bright and nickeled.

More Spelling Bee Suggestions.

Some weeks ago we gave some "Suggestions for a Spelling Bee," based upon the names of certain articles in a chemical journal, which may, perhaps, have given a shock to those of our readers who were not previously familiar with the strange language used to express their thoughts by the professors of the occult science of chemistry. Should they wish to make further researches into this interesting subject we should recommend a study of the May number of the same journal, where ample food for reflection on the possibilities of the English (?) language in the production of compound words will be found. If they wish it, they can there be instructed in the preparation of paradiazometatoluenesulphonic, parametho-xymetasulphaminebenzoic, and para-amidoorthotoluenethiosulphonic acids. These processes, as we should naturally expect, appear to be lengthy ones. Many pages are devoted to them, portions of which are a trifle abstruse. As, for instance, when we are told that an eminent chemist "when studying paraamidotolueneorthothiosulphonic acid had changed this thiosulphonic acid into the corresponding sulphinic acid. On diazotizing the paraamidoorthotoluene-sulphinic acid, and decomposing the diazo compound in absolute methyl alcohol, he obtained a non-crystallizing acid which he called oxymethyltoluene-sulphonic acid."

A question that occurs to one's mind in this connection is whether the initiated, in general conversation, pronounce these awe-inspiring words in full, or whether they have pet names for them. If not, the articulation of these terms must take up a great deal of their time. Probably they have to undergo a special course of training in it.

A foreign journal speaks of an invention which has just been perfected in Liverpool, and which it is thought will effect a revolution in lamp wicks. A small piece of asbestos web is inserted in the end of an ordinary lamp wick for about ¾ inch, a very small portion of the asbestos web appearing above the wick, and the result of this arrangement is to increase the power and usefulness of the wick. It is claimed that experiments have indicated an increase in the intensity of the light of an ordinary lamp from six candles to eight candles, while the life of the new wick is asserted to be practically everlasting, an experiment conducted with a ship's side light for 600 consecutive hours showing no appreciable effect on the wick. It is also claimed that no trimming is required after the first adjustment, and that the combustion is so perfect that neither odor nor smoke can be perceived.

TRADE REPORT.

The Iron Market.

Stagnation prevails in all the leading markets and in all branches of the Iron trade. Very few plants throughout the country are running anywhere near full capacity and restriction of output or complete closing down is the order of the day. Consumption of raw and finished goods is at a low ebb, a good many orders have been canceled, and in many instances delivery of goods is withheld until it becomes quite clear that prompt payment is forthcoming.

The one danger feared is that the financial stringency, which has until now been confined to the wholesale trade and to manufacturers, will spread to the retailers throughout the country. The discharge of many thousands of men will restrict sales and will put pressure for credit upon the small merchants.

Pig Iron.—The New York market is dull, and new business is scarce. Deliveries on old contracts continue fair in volume, although postponements are quite frequent. Lower prices are being made for Southern Iron. We quote Northern brands $14.25 @ $15 for No. 1; $13.50 @ $14.50 for No. 2 at tidewater. Southern Iron, same delivery, $13.75 @ $14.50 for No. 1; $12.25 @ $13.25 for No. 2; $12 @ $12.25 for No. 3; $12 @ $12.25 for No. 2 Soft, and $12.50 @ $13 for No. 1 Soft.

Philadelphia advices show the Pig Iron market in that section to be extremely dull, price being no inducement, except to those who need material. Money is scarce, even with the best concerns, so that the bulk of the business done is in small lots, and in most cases at about the figures quoted below, although buyers with money in their hands can get almost anything required at concessions from quoted rates. Quotations for Philadelphia and nearby points are about as follows:

American Scotch, No. 1X	$16.00	@	...
American Scotch, No. 2X	15.00	@	....
Standard Penna. (Lake Ore), No. 1x	14.75	@	$15.25
Standard Penna. (Lake Ore), No. 2x	14.00	@	14.50

Production is being largely restricted everywhere in the Pittsburgh district, which is undoubtedly good policy, and will favorably affect the situation. Numerous furnaces have blown out and others are likely to do so this month. Buying is reported as about at a standstill in Pittsburgh, and is not likely to improve until there is more activity at the mills. Quotations as follows:

No. 1 Foundry	13.25 @	13.50	cash.
No. 2 Foundry	12.25 @	12.50	"
Charcoal Foundry No. 1	17.00 @	18.00	"
Charcoal Foundry No. 2	16.50 @	17.00	"

Advices from Chicago report that inquiries for round lots of Southern Pig Iron have sprung up recently, and if they were all to be placed the volume of business would be remarkably good in that line. Buyers, however, seem to be looking for special bargains and will not pay present prices for future delivery. Purchasing is therefore confined to hand-to-mouth quantities, on which current prices are being paid. Local Coke is neglected and Lake Superior Charcoal has been without movement for some time. A better tone financially is reported along the Pig-Iron houses so far as collections are concerned. Shipments, however, are so extremely light and new business is so small that it amounts to almost a complete suspension of trade. The following quotations are subject to concessions for prompt cars and immediate shipment.

Lake Superior Charcoal	$16.00 @	$16.25	
Local Coke Foundry, No. 1	13.50 @	14.00	
Local Coke Foundry, No. 2	12.75 @	13.00	
Local Coke Foundry, No. 3	12.50 @	12.75	
Local Scotch	14.00 @	15.00	
Ohio Strong Softeners	15.75 @	16.25	
Southern Silvery, No. 1	@	14.50	
Southern Silvery, No. 2	@	14.00	
Southern Coke, No. 2	12.75 @	13.00	
Southern Coke, No. 3	12.25 @	12.50	
Southern, No. 1, Soft	12.65 @	13.00	
Southern, No. 2, Soft	12.00 @	12.25	
Tennessee Charcoal, No. 1	16.50 @	17.00	
Alabama Car Wheel	@	18.85	
Hocking Valley, No. 1	15.25 @	15.50	
Jackson County Silvery	16.75 @	17.00	

The volume of business in Pig Iron in Southern markets continues very restricted. The demand from the East and the Northeast for Southern Iron has fallen off, so that sales for the week are smaller than they have been at any time during this season. A further reduction in the output is reported, but there is an ample supply of Iron offered for all the wants of the trade. What little demand there is for Pig Iron is mainly for foundry grades, and is freely furnished at the inside quotations, which are the same as a week ago, namely:

Foundry.

Southern Coke, No. 1	$12.75 @	$13.00	
Southern Coke, No. 2	11.25 @	11.50	
Southern Coke No. 3	10.75 @	11.00	
Ohio Soft Stone Coal, No. 1	15.50 @	16.00	
Ohio Soft Stone Coal, No. 2	14.50 @	14.75	
Lake Superior Coke No. 1	15.00 @	15.25	
Lake Superior Coke No. 2	14.00 @	14.25	
Hanging Rock Charcoal, No. 1	18.50 @	19.00	
Hanging Rock Charcoal, No. 2	17.50 @	18.00	
Tennessee and Alabama Charcoal, No. 1	14.75 @	15.00	
Tennessee and Alabama Charcoal, No. 2	13.75 @	14.00	

Car Wheel and Malleable Irons.

Standard Southern Car Wheel	16.75 @	18.00	
Lake Superior Car Wheel and Malleable	17.25 @	17.50	

Metal Market.

Pig Tin.—There has been moderate fluctuation in prices, and the net result is that the market stands practically the same as it was a week ago. The exception is that sales of spot stock and deals in "futures" are harder to work in the face of an apparent reduction of 1600 tons in the visible supply on this side of the Atlantic during the past month, and data showing shipments of only 900 tons from the Straits during the last half of July, or a total of 2425 tons for the entire month, against 3500 tons in July last year. Monetary stringency has some weight as an offset to the McKinley duty and the 8300 tons in stock here, as per Metal Exchange records, is an obstacle of no mean description. In any event the heavy spot stock has thus far proved a stumbling block in the way of efforts to raise prices to a parity with present cost in foreign markets. Meanwhile the demand from consumers is very moderate, and principally for small lots at a time. Current prices are for Banca and Straits Pig, 21½¢ and 21¢, respectively, for lots of less than 500 lb. These prices would be considerably shaded on orders for larger quantities for spot cash.

Copper.—Business has been quite as slow as it was during last week and evidence is wanting of any increase in demand from home consumers. Naturally, prices have softened and the market has shown additional signs of weakness. Still, producers hold against adverse conditions in remarkably good form, and, up to date, the decline appears more superficial than real. Orders are small, and of a hand-to-mouth character, and jobbers are holding very light stocks.

Sheet Copper.—The demand is of the slightest nature. Prices for small lots are, however, unchanged, as per list.

Pig Lead.—Business to a fair extent has been effected, but the market is feverish, with rather weak undertone, suffering more or less from the financial situation and general depression in business circles. The best offers of stock for prompt or future delivery receive but little attention. Quotations for small lots are nominally 4¢, and 3.75¢ for ton lots; but these figures might be slightly shaded for cash orders. Consumption shows some falling off, with little to indicate any immediate revival.

Spelter.—Free offering has failed to stimulate business in the slightest degree. Enough stock comes out to keep prices down, but nothing points to any increase of demand in the near future. Western Spelter in small lots is quoted at 4.75¢ @ 5¢.

Sheet Zinc.—The present month, which is always the dull season for this

material, is an exceptionally quiet one this year. Business is almost at a standstill, and the demand, such as it is, is of the slightest. Prices are, however, steady at 7¢ ℔ lb on small quantities, and 6¼¢ for 600-lb casks.

Antimony.—The market remains dull and prices are unchanged at 10½¢ @ 11¢.

Tin Plate.—There has been no improvement in the demand for spot stock or future deliveries and the market presents a dull appearance. Sellers' prices remain about as they were a week ago, but concessions have been the rule where anything in the nature of desirable orders was involved. Importers have been sending over very light orders for foreign plates, not desiring to lay in any unnecessary stocks in view of possible tariff changes. Jobbers are for the same reason, and also on account of the money difficulty, holding off purchases of more stock than they can dispose of out of hand. Shipments of Tin Plates from British ports for the week ending July 22 showed a considerable falling off from the previous week. Business in Tin Plates in Great Britain was reported by cable on August 2 to be quite flat, and Ternes and Black Plate were at the same time quiet and apathetic, makers claiming that present prices leave no margin of profit and that they cannot do business on the ruling rates. Stocks in makers' hands were large and increasing, with light orders only coming in. The *Iron and Steel Trades Journal* of London on July 22 states that the business in Ternes was light on account of "the home trade in America having robbed the English market of considerable business." In the New York market the demand for Charcoal Brights is very small, prices in this line showing some signs of weakness. Spot cash could probably obtain concessions for moderately large orders of 12½¢ to 25¢ off lowest quoted rates for imported Brights. Coke plates are in intermittent demand, but for light amounts, principally from canners who have not laid in quite sufficient stock. The business done in this material is, however, of a very narrow character, and does not appear to approach expectations. Some jobbers, however, see indications of a revival in the fall, when canners may be forced to purchase. Many of the newly started canning factories in the South have held over operations for this season on account of the impossibility of obtaining accommodations from the banks, and the same reason has militated against the industry further North. For domestic Ternes there is a fair, steady demand, which is well filled by those works which are now running. The financial depression by causing the abandonment of much projected building has told on the market for roofing plates to a great extent. Prices of imported plates are slightly lower, except for special brands.

Solder.—Low prices for tin and lead have caused an easing off in prices for Solder, which is quoted at 13½ @ 14½¢ for half and half (guaranteed); and 11½¢ @ 12¢ for No. 1.

Chicago Report.

Scrap.—There is still no demand whatever for Old Material, and the following buying prices are therefore only nominal:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$10.00	....
Machinery Cast	7.50	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	5.00	....
Burnt Iron and Grate Bars	4.00	....
Sheet Iron and Hoops	3.00	....
Plow Steel and Breaking Stock	6.00	....
No. 2, such as Shovels, Hoes, &c	4.50	....
Old Boilers—whole (Iron)	6.00	....
" (Iron)—cut in single Sheets and Rings	9.00	....
Old Gas-Pipe and Boiler Tubes	6.00	....
Cast Borings	3.50	....
Turnings	5.00	....
Horseshoes	10.00	....
Copper Bottoms	....	7 ¢

Heavy Brass	....	7½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2½¢
Zinc	....	2¾¢
Rubber	....	2¾¢

Anthracite.—There is very little movement among either retail dealers or consumers, and shippers think that trade is likely to be dull for some time in sympathy with other branches. They continue to quote carload lots of 12 net tons as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

THE FIRM OF JOHN MERRY & Co., New York, who are well known to buyers of Sheet Metals, have been succeeded by the firm of Merry & Clark, importers of Tin Plates, Sheet Iron and Metals. Geo. E. Merry, who has for many years been associated with the old firm, needs no introduction to the trade. Elton W. Clark, the other partner, comes from the Wall street center, and, we understand, is a man of considerable ability and experience in foreign and domestic financial matters. It is the intention of the new firm to continue at 535 to 547 West Fifteenth street, New York, where old friends will receive a cordial welcome.

CONDITION OF THE

Hardware Trade.

THE VOLUME OF BUSINESS in all parts of the country continues to be very small, orders being strictly confined to the requirements of dealers. Manufacturers and jobbers are making very little effort to sell goods and are confining their energies to making collections and keeping down expenses. In many instances orders previously given are being reduced or countermanded, and in some cases deliveries deferred. Collections continue difficult, although some houses report an improvement in this respect. Stocks of manufactured goods are not in general large, manufacturers having during the whole of this year pursued a very conservative policy in this respect, and are now reducing their production to prevent any great accumulation of goods. This policy will save the market the danger of being depressed by large stocks of goods which manufacturers might find themselves forced to sacrifice. The improvement in the financial situation during the week has had an encouraging effect upon the business community, and the opinion is very general that the reaction has begun. Among the important factors in this are the exports of produce and securities and the consequent importations of gold. Our exports of hay on account of the scarcity of fodder in Europe promise to be very large, and the prospect of this has led to a great demand for Bale Ties, on which a scarcity is apprehended. The low prices which have prevailed for a long time in manufactured Products seem to remove the danger of any sensational decline in the market.

Advices from Chicago.—Shelf Hardware jobbers report continued dullness which is felt in every line, the demand for Builders' Hardware being far below the average at this time of the year, while staple goods are moving in very light quantities only. Jobbers are receiving reports from manufacturers that they are closing up their establishments to wait for a revival of trade. Purchases being made here for stock are now only about one-quarter of their usual volume. If this rate holds good throughout the country the stock of goods held in the wholesale Hardware trade will soon be down to such a low point that a revival in the demand cannot fail to cause such a rush for orders from all sections as to overwhelm manufacturers with business. The congested condition of the Hardware trade thus appears likely to result at some time in the future in activity fully as pronounced in its way as the present dullness. This is a contingency to be guarded against by those who are able to keep their stock of goods in fair condition. Much is heard now of the generally excellent condition of the farmers, who have had two good years, enabling them to pay off mort-

gages, while all crops are fair this year with a heavy demand from abroad. Collections are growing better, if anything, showing that people are liquidating their indebtedness as fast as possible, thus putting themselves in good financial shape.

Cut Nails.—The majority of mills producing Cut Nails are either closed or running very light. The movement of goods is very small and prices still rule at $1.05 for carload lots at mill, but this price can be shaded for desirable specifications in both Iron and Steel Nails. Small lots from store in New York are quoted at $1.30.

Advices from Chicago.—The demand for Cut-Steel Nails is still confined to small lots only, and the idle factories are offered no encouragement whatever for resuming operations. Prices remain unchanged at $1.20 to $1.25, Chicago, for carload lots from factory, and $1.25 to $1.30 for small lots from stock.

Wire Nails.—The makers of Wire Nails are still endeavoring to make some arrangement among themselves which will restore the business to a profitable basis, and they express a good deal of confidence in the ultimate success of these efforts. In the meantime they have agreed to keep all the mills closed during the month of August. Stocks in makers' hands are light, and in most instances assortments are badly broken. For carload lots at mill $1.35 is the regular price, but sales have recently been made at figures shading $1.30.

Advices from Chicago.—Manufacturers are now having weekly meetings for discussion of ways and means to improve the condition of trade. They were not able last week to arrange matters finally for the perfection of a plan to restrict production, which is under contemplation, but the subject is to be considered at further meetings. It is likely that the factories will be kept closed during the month of August, as stocks have not yet been reduced to a point which makes it necessary to resume operations. Prices are unchanged at $1.45 Chicago, for factory lots and $1.55 to $1.60 for small lots from stock.

Barb Wire.—There is very little doing in this article, but prices remain firm at $2.45 to $2.50 for carload lots of Four-Point Galvanized at mill, and small lots from store at the usual advance.

Advices from Chicago.—Stagnation prevails in this branch of trade. The only movement reported from any part of the country is from the extreme South, where planters and farmers have harvested their crops and are now beginning to purchase Wire to improve their farms. This movement, however, is not of sufficient importance to extend to the factories in this vicinity, which are still closed. Prices can be quoted as before at $2.10 for carload lots of Painted and $2 50 for Galvanized. Jobbers maintain quotations on small lots from stock at $2.30 and $2.70 respectively.

Traveler's Drinking Cup.—T. H. Clifford, 265 Dearborn street, Chicago, is putting this article on the market, a description of which appeared in *The Metal Worker* several weeks ago. The Cup is sold to the trade at $3 per dozen.

Glass.—The condition of the Glass trade is much the same as that of other lines. There is some business being done, in amount of course small compared with that of previous years, and collections are slow. Reports from Western cities indicate a partial cessation of building operations, which condition, to a greater or less extent, is found throughout the entire country. On the other hand, stocks of Glass are not large and prices are as well maintained as they have been for the past six months. The date upon which the factories will resume work is undecided, although September 1 is the usual time for beginning. Prices at which Glass is being sold in Philadelphia, Baltimore and Southern markets are reported as still being somewhat below the rates established by the National Window Glass Company, and it is understood that imported Glass quotations are shaded in some cases. Quotations on Glass remain unchanged, as follows: American Window Glass, less quantities than carloads, 80 and 10 per cent. discount, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—Prices are fairly well maintained at present rates, with a minimum amount of business doing. The following are the prices paid for Old Rubber delivered in New York, except as otherwise stated:

Car Springs, ton lots, ℔ lb.		@	$0.03¼
Rubber Shoes, carloads, delivered at factory, ℔ lb.		@	.03⅛
Rubber shoes, less than carloads		@	.03
Large Hose, ℔ ton		@	9.00
White Wringer Rolls, ℔ lb.		@	.04¼
White Wringer Rolls, good grade	04½	@	.05
White Syringes, ℔ lb.		@	.05

Old Rags, Paper, &c.—Business continues practically at a standstill, the demand from Paper mills being very limited. The following are the current prices quoted for Old Rags, Paper, &c., delivered in New York:

No. 1 White Rags	℔ lb 3	@	3⅛¢
No. 2 White Rags	℔ lb 2	@	2⅛¢
Mixed Rags	℔ lb		1¼¢
Blues and 3ds	℔ lb		1¼¢
Hard Sized White Shavings	℔ lb		2¾¢
No.1 White Book Shavings	℔ lb 2¼	@	2⅜¢
No.2 White Book Shavings	℔ lb 1½	@	1¾¢

No. 2 Mixed Shavings	℔ lb		½¢
No. 1 Printed Books	℔ lb 1	@	1¼¢
Ordinary Mixed Books	℔ lb ½	@	¾¢
Newspapers	℔ lb		½¢
No. 1 Manila Paper	℔ lb 1⅛	@	1¼¢
No. 2 Manila Paper	℔ lb ⅞	@	1 ¢
Bogus Paper	℔ lb ⅝	@	¾¢
Common Paper	℔ lb ⅜	@	½¢
Straw Chips	℔ lb ½	@	⅝¢
Binders' Clippings	℔ lb ½	@	⅝¢
Jute Butts	℔ lb		1⅛¢
No. 1 Jute Bagging	℔ lb 1¼	@	1⅜¢
Mixed Bagging	℔ lb		1¢
No. 2 Bagging	℔ lb		¾¢
Hemp Twine	℔ lb		2¼¢
Manilla Rope	℔ lb		2¼¢
Jute Rope	℔ lb 1½	@	1¾¢
Mixed Rope	℔ lb ¾	@	⅞¢

Old Metals.—There is little business doing in this class of material. Prices depend largely upon pressure to buy or sell. The following are fair quotations now current for Old Metals in New York, subject to the conditions stated:

Heavy Copper	℔ lb	9½¢
Light and Tinned Copper	℔ lb	8½¢
Heavy Brass	℔ lb	7¢
Light Brass	℔ lb	6¢
Lead	℔ lb	3½¢
Tea Lead	℔ lb	3¼¢
Zinc	℔ lb	2¾¢
No. 1 Pewter	℔ lb	14¢
No. 2 Pewter	℔ lb	7¢

Mixed Bagging	℔ lb	1 ¢
No. 2 Bagging	℔ lb	¾¢
Hemp Twine	℔ lb	2½¢
Manila Rope	℔ lb	2¼¢
Jute Rope	℔ lb 1⅛ @	2 ¢
Mixed Rope	℔ lb ¾ @	⅞¢

Trade Notes.

THE NUMBER OF PEOPLE who read the advertising pages before they give their attention to the other part of a publication is by no means so small as is generally imagined, and there is not a little excuse for the preference shown when we consider the tastefulness displayed in the presentation of advertisements now-a-days. A little pamphlet issued by the Huette-Barler Mfg. Company, Chicago, Ill., is a wonderfully neat example of the attractive advertising circular. The outside cover bears the inviting legend "How to shine in home and office" and the inner pages develop this idea. The first is a picture of the old-fashioned method of shining with the foot on a broken box and pretty much of everything daubed with blacking. The second page shows the work done with the assistance of a bootblack; the third illustration show Barler's Shine Cabinet as used in the office; the fourth, the fifth, sixth and seventh as used in the home by the various members of the family for various purposes. This cabinet is a neat little device fastened to the wall.

SIDNEY SHEPARD & Co., Buffalo, N. Y., send out circulars respecting Yager's Soldering Salts, which they adopted at their works some years ago. Their experience with it was so satisfactory that they began to sell it, and now have a large trade in the Salts, supplying tinware factories, packing houses, electric light companies, &c. The Salts are said to be unlike acids, as they emit no fumes or smells.

THE FURNACE & SHEET METAL WORKERS' ASSOCIATION of Rochester, N. Y., had their annual outing at Newport, N. Y., July 26, and indulged in a variety of sports and games.

THE MATAWAN ENAMELED BRICK, as displayed by the J. L. Rue Pottery Company, Matawan, N. J., in the windows of their New York office at 54 East Twenty-third street, are interesting to fire place and grate dealers. They are not only shown in a variety of colors,

but each color is in several tints and several are attractively mottled. These effects are increased by the perfectly smooth surface of the enamel, which is remarkable in being free from craze. To accomplish this end has been the effort of many manufacturers, and the success made in the Matawan Brick is conceded in its adoption by such architects as R. H. Hunt and McKim, Mead & White, who have previously used English brick exclusively.

THE E. W. BLISS COMPANY, Brooklyn, N. Y., issue a very elaborate series of catalogues in connection with their exhibit at the World's Columbian Exposition in Chicago. These publications were put out for the purpose of explaining to foreigners, as well as to English speaking visitors, all the details and particulars of their machinery. The publications of the series are five in number, and among the goods named are the Stiles Drop Hammers, the Stiles Friction Roll Drop Toggle Presses of various kinds and sizes, Adjustable Power Presses, Open Back Power Presses, Central Swing Power Presses, Power Punching Presses, Geared Power Punching Presses, Deep Throat Power Presses and the Double Crank Presses, the latter comprising an extensive line. The special feature of these publications is not so much the neat illustrations and excellent topography, but the parallel accounts published in the three languages, English, French and German. We think this will be particularly appreciated, for among the visitors at Chicago are large numbers of German and French metallurgists and machinists who are more familiar with machinery than they are with the English language, and will appreciate the assistance of a description in their native tongues.

THE ILLINOIS ROOFING & SUPPLY COMPANY, 203 Lake street, Chicago, publish a remarkably strong testimonial in their advertisement in this issue. They are agents for "Gilbertson's Old Method" Roofing Tin, and the testimonial, which is from the Commissioners of South Dakota to the World's Fair, says that the roof of this tin on the South Dakota State Building, after a long and severe trial, has proved itself to be the best roof of any of the buildings on the World's Fair grounds. It is still as perfect as the day it was put on, which was early last October. No paint or varnish of any kind was applied to the surface of the tin, and yet it shows no signs of rust. The Illinois Roofing & Supply Company guarantee that each box of IC 20 x 28 shall weigh 240 pounds net, without the box, covered with 36 pounds of best terne coating, and that each sheet shall be made of softest steel and stamped carefully with the brand and thickness. They further state that no Wasters are sent to the United States, therefore it is only possible to secure the best.

THE MCCULLOCH IRON WORKS at Northeast, Md., which have been shut down for some time, will, it is stated, start up again at an early date. During the shut down two annealing furnaces were installed by Wm. Swindell & Bros., the engineers and contractors of Pittsburgh, and when the works resume operations they will be able to turn out both galvanized and black sheets.

IT WAS STATED a few weeks since that the Joliet Sheet Steel Rolling Mill Company, Joliet, Ill., were preparing to resume operations at their plant. The matter has since been reconsidered by the management and they have decided to allow the works to remain idle for the present. Quite a number of workmen who went to Joliet, expecting employment with this concern, are now without means of support.

DULL TIMES and a tight money market have caused the Guernsey Rolling Mill Company to indefinitely suspend their project to build new sheet mills at Cambridge, Ohio, for which purpose the company were organized.

THE BRITTON ROLLING MILL COMPANY of Cleveland, Ohio, have decided to go ahead with the erection of a number of sheet mills projected last year. It is expected that two additional mills will be ready for operation within a short time, the bed plates, housing and other equipment having been secured some time since and are ready to put in position at any time.

IN ALL PROBABILITY the National Rolling Mills of the National Tube Works Company, McKeesport, Pa., will resume operations during this week. For some years this concern have not signed the Amalgamated Association scale, but have always paid wages called for by that scale, and it is probable that operations will be resumed this year with the same understanding.

THE DETROIT FOUNDRY EQUIPMENT COMPANY, Detroit, Mich., have opened a New York office at 182 Front street, in charge of J. Gilmour.

THE WHITAKER IRON COMPANY, Wheeling, W. Va., are operating their sheet mills and galvanizing shops to full capacity. There is no talk of a shut down and prospects are said to be good for a steady run.

A LARGE NUMBER of men have been laid off at the works of the Peck, Stow & Wilcox Company, Southington, Conn.

UNITED INDURATED FIBER COMPANY of New Jersey had their factory at Lockport, N. Y., destroyed by fire July 28. It was caused by an explosion in one of the bake ovens, resulting in the destruction of all their manufactured goods and stock in process, together with the building and machinery. It is their intention to rebuild at once, but so far as producing anything there it amounts to a total stoppage until a new plant is installed. Their factory at North Gorham, Maine, makes many goods of the same nature, so they are still in a position to partially execute orders, although since reducing the price on this ware in January of the current year, notwithstanding additions to their manufacturing facilities, they had but recently been in a position to execute orders promptly.

THE BRONSON SUPPLY COMPANY, 90 Beekman street, New York, are about to add the product of two or three new factories to their present line for the fall trade. The articles are of a kindred nature to what they now handle. The Bronson Supply Company have a full stock of their Never Break ware on hand, and will thus be in a position at the beginning of the fall season to fill all orders promptly.

THE sheriff of Cook County took possession on July 29 of the manufacturing plant of the Goulds & Caldwell Company, manufacturers of pumps, pipes, hose and belting, and general mill contractors, at 22 and 24 North Canal street, Chicago. The sheriff's act was in pursuance of a confession of judgment in the Circuit Court in favor of the National Bank of America for $20,000.

THE AMERICAN TUBE & IRON COMPANY, the second largest tube and pipe manufacturers in the United States, with plants at Middletown, Pa., and Youngstown, Ohio, have made application for the appointment of receivers.

THE Lorain Brass Works at Elyria, Ohio, have filed a deed of assignment.

WORTHINGTON pumping engines will be used for the water supply of the City of Osaka, Japan.

THE Rome Brass Works have shut down.

UNIVERSAL SAD IRON COMPANY, Milwaukee, Wis.: The Universal Sad Iron. Small sheets in the shape of the Universal Sad Iron, held together by an eyelet, the outside sheets having colored illustrations of the article, are sent out with the compliments of the company. Description, list prices and other information are contained within the covers in a compact and comprehensive manner.

THE PLUME & ATWOOD MFG. COMPANY, New York and Chicago: Royal Lamps, Brass and Copper Goods. The catalogue devoted to Lamps is an artistic production of convenient size, and illustrates Royal Lamps in a variety of kinds and styles. The catalogue referring to Brass Goods gives price-lists of Brass in various forms, Brass and Copper Wire, Copper Rivets and Burs, Brass Butts, Chain, Ferrules, Curtain Rings, Heel Plates, Box Rings, Bells, Drawer Pulls, Banner Lamps, &c.

ODELL HARDWARE COMPANY, Greensboro, N. C.: Illustrated pamphlet No. 8, of 84 pages, devoted to Farming and General Store Goods, including Plows, Barrows, Road Scrapers, Cultivators, Hoes, Steel Fencing, Shovels, Spades, Rakes, Chains, Refrigerators, Wire Goods, Screens, Lawn Mowers, Pumps, Freezers, Cider Mills, Wringers, Hammocks, Milk Shakes, Ice Shaves, Fly Traps, Lawn Sprinklers, Barb Wire, &c. A general Hardware list is issued in addition to this.

A. F. SHAPLEIGH HARDWARE COMPANY, St. Louis, Mo: Fall Catalogue of Seasonable and Holiday Goods. The book contains 56 pages and illustrates Axes, Saws, Scoops, Corn Shellers, Family Grist Mills, Huskers, Pearl Agate Ware, Puritan Ware, Hollow Ware, Meat Cutters, Stove Boards, Shovels, Tongs and Pokers, Coal Vases, Dampers, Electric Bell Sets, Registers, Skates, Sleigh Bells, Sleds, Bicycles, Clocks, &c.

E. F. REECE, Greenfield, Mass.: Screw Cutting Tools. The Reece Improved Hand Bolt Cutters or Screw Plates are illustrated with descriptions and prices in a catalogue. These, with interchangeable tap and die holders for Bit-Brace, &c., are designed for blacksmiths' and machinists' use. Stock, Tap Wrench, and Tap and Dies are put up in sets in cases, of a variety of sizes, adapted for various kinds of work.

A tariff war has commenced between Germany and Russia. The latter country is about to add 50 per cent on to her maximum tariff on German imports in reprisal of similar action on Germany's part in the matter of Russian goods. The opportunity should be a good one to market the agricultural productions of the United States in Germany.

Current Hardware Prices.

AUGUST 4, 1893.

Note.—The quotations given below represent the Current Hardware Prices which prevail in the market at large. They are not given as manufacturers' prices, and manufacturers should not be held responsible for them. In cases where goods are quoted at lower figures than the manufacturers name, it is not stated that the manufacturers are selling at the prices quoted, but simply that the goods are being sold, perhaps by the manufacturers, perhaps by the jobbers at the figures named.

The character @ is used to indicate a range of price; thus discount 50&10@50&10&5 % signifies that the goods in question are sold at prices ranging from discount 50 and 10 % to discount 50 and 10 and 5 %.

News and Notes.

A larger proportion of customs duties at New York have recently been paid in gold coin than at any time since April, 1883.

A dispatch from Ottawa states that the figures of Canada's export trade for the fiscal year ending June 30, 1893, have just been compiled, and show that the exports exceed those of the previous year by $1,250,000, and are the greatest on record, aggregating $115,187,666. In 1892 the export trade amounted to $113,963,375, and in 1891 to $98,417,296.

Croton water will, experimentally, be purified by an electrolyzing process recently tested by the Health Board. Serious complaints have recently been made by New York residents of the quality of the city's water supply.

A New York syndicate have, it is said, secured control of the cork trade through the country by the combination of the five largest cork works.

A small species of worm has made its appearance in the Northwest which is reported to be destroying whole tracts of forest trees in some of the heaviest timbered districts of Washington State.

Failures among farmers in Great Britain for the first half of the year were 40 per cent. over those of the corresponding months of last year. The agricultural depression is said to be unprecedented. Thousands of unemployed farm laborers are hovering in the outskirts of London, and more than 16,000 persons engaged in agriculture are living in sheds, barns, tents, vans or the open fields.

Political and financial troubles in South and Central America have, it is said, prevented the expected flow of visitors from those countries to the World's Fair. Steamship agents state that there has been practically no increase of travel from the South and Central American States to this country this year, although every inducement has been offered to tourists and the fair widely advertised.

A financial novelty has been started on the Kootenai Lake, British Columbia. It is a floating bank which goes round in a steamer and transacts business by turn at the various towns on the lake, none of which are large enough to support such an institution single-handed.

The New York, New England and Northern Railroad was incorporated this week, with a capital of $3,000,000. A. A. Macleod is understood to be the controlling spirit of the undertaking.

A serious scarcity of vessels for carrying California wheat exists at San Francisco. Wheat freights have consequently made a decided advance. The increased demand for tonnage is occasioned by the wheat growers disposing of their crops immediately after they are harvested, the banks refusing to advance them money on warehouse receipts.

Indictments have been made at Portland, Ore., against 15 persons, 8 of them being ex-Federal officials, for smuggling opium and Chinese laborers into the Washington and Puget Sound districts.

W. R. Lawson of the London *Financial Times*, who has just completed a somewhat extensive tour through the Southern States, is reported as saying: "I am going back to England with quite a cheerful feeling in regard to Southern roads. In fact, I think the South looks as though it would be the most prosperous part of the country this year. Iron industries are bad, but almost everything else looks well. The truck farming has increased enormously since I visited the South last. It is becoming a great source of revenue for both the people and the railroads."

Estimates for this year's Delaware peach crop put the probable yield at over 5,500,000 baskets. This will be by far the heaviest crop known within the last 25 years.

Dr. Wheeler, who was sent by the Treasury Department to Europe to inspect the sanitary condition of the more important seaports of the Continent, and to inquire into the arrangements for shipping immigrants, has returned to this country. He reports that the sanitary condition of the cities visited, namely, Hamburg, Bremen, Rotterdam, Antwerp, Marseilles and Naples, is far better than was the case last year. Every precaution is, he says, being taken to prevent the approach of cholera and to hold it in check in the event of its appearance.

The long distance telephone lines between London and Paris have almost superseded the telegraph as a means of communication between the stock exchanges of the two cities.

The Mexican Congress has authorized the Executive Department for the next five years to make contracts granting franchises and concessions to companies that guarantee the employment of capital in the establishment and development of new industries in the republic, upon certain conditions, among the principal of which are that the minimum capital to be invested must be $250,000 and that concessionaires must guarantee their compliance with the contracts by making deposits in bonds of the public debt. The duration of franchises will be graduated according to the importance of the industry, but will in no case exceed ten years. The capital will be exempt from all federal taxation, and the concessionaires will be permitted to import, once only, free of duty, the machinery, apparatus, tools, construction materials and other necessaries for their factories and buildings.

The drought in Northern Mexico has had the effect of causing the owners of haciendas to turn their attention seriously to the subject of irrigation.

In striking contrast to her big neighbor—Australia—New Zealand has been enjoying a year of unbroken prosperity. The colony has had no boom, but an extremely profitable trade has been steadily and surely growing up for the past five years. Business has been uninjured by the bank crashes in Australia, and it is said that deposits in the New Zealand banks are as safe as if in the Bank of England. The outlook is regarded as very bright for a steady growth of progress and prosperity.

The prompt issue of consular reports on trade and commercial subjects is a feature of the State Department which is much appreciated by manufacturers and exporters.

President Diaz is credited with the intention of inaugurating forthwith some radical economies in the administration of Mexico, prominent among them being a material reduction in the standing army of the republic.

Renewed activity is observed in the old oil fields in West Virginia.

The Canadian Pacific Railway Company contemplate the employment of electricity in drawing trains up Kicking Horse Canyon.

An ocean race of 15,000 miles, for a purse of $5000 in gold, between three big ships engaged in the carrying trade, commenced on July 28 from Philadelphia. The vessels are all English, and each carry 125,000 cases of petroleum, their destination being Calcutta.

Governor Lewelling of Kansas has started a project for opening up direct trade relations between Kansas and other Western States and European seaports by way of the Gulf of Mexico.

THE METAL WORKER.

Stove Repairs.

Already the dealers in stove repairs, as well as the stove manufacturers, can detect unmistakable signs of a large demand in this direction. The last winter played no unimportant part in creating this demand, as its severity taxed all kinds of domestic heating and cooking apparatus beyond what is usual, and left them in no fit condition to do service under similar conditions. Another important factor is the prevailing idea that money will be more scarce before it is more plenty, and instead of expending the sum necessary for a new stove, a tithe of it will be spent on necessary repairs. Following the same line of thought brings up the old question of stove construction, which frequently a correspondent will notice by saying that little consideration is given by the maker to the man who repairs a stove. Bolts and nuts are placed out of sight and out of convenient reach. As a result there is trouble over the price charged for a few small castings which have taken a considerable time to put in place. It is useless to worry over this question, and the proper thing for the repair man to do is to provide a complete set of tools and devices to enable him to surmount his difficulties quickly.

Misrepresenting Industries.

It is a pity that reputable journals should, for party ends, resort to methods which, to say the least, must be characterized as disingenuous. Statements have recently appeared in partisan newspapers in regard to the condition and prospects of certain manufacturing industries which appear to have been deliberately designed to produce a misleading and injurious impression on the minds of those who are not well acquainted with the real state of the matter. These questionable tactics have of late been very freely used by the opponents of the American tin-plate industry, who have let slip no opportunity of disseminating and enlarging upon any items of intelligence, or even mere rumors, in connection with domestic tin-plate works, which may be calculated to discredit the industry with the general public. The strenuous and honest efforts which have been made by home manufacturers to build it up have been not only ignored but in many cases willfully misrepresented and doubts thrown on their integrity. Stoppages of works for the usual summer repairs, or on account of the heat, or temporary suspension of production caused by the general dullness of trade, have been greedily seized upon by certain papers and magnified into failures and embarrassments.

A Case in Point.

Quite recently the New York *Evening Post* printed a long article purporting to show the evil effect of the McKinley tariff upon the tin box trade of Brooklyn. The condition and prospects of three of the principal concerns manufacturing tin boxes in that city were given—ostensibly from information afforded by members of those firms—as being quite seriously depressed and gloomy, owing to the tax on tin plates. One of these concerns was the well-known firm of Somers Brothers, of whom it was said that they had attempted the manufacture of sheet tin last year, but gave it up two weeks ago. As a matter of fact the works have been running most successfully up to a short time ago, when they were closed down temporarily for the usual annual overhaul, and also because of the general dullness of trade in all its branches, rendering a short rest from production desirable, and especially so during the heated term. So far from relinquishing the manufacture of tin plate, the Somerton Tin Plate Works will be started full again on September 1.

Eccentric Architecture.

Building is a matter in which eccentricity is very apt to show itself on the part of individuals who are otherwise supposed to be in complete possession of their senses. Instances are numerous in ancient and modern history in which persons have set to work to build odd dwelling houses, or other erections, embodying some extraordinary ideas of their own, in design, construction, or decoration. Occasionally the thing is done purely for notoriety, but more often it is the outcome of some mental kink on the builder's part. Such objects are, in fact, usually the work of "cranks." The late Duke of Portland, one of the wealthiest of English peers, was a remarkable case in point. This individual expended immense sums and gratified his mental twist—for he was undoubtedly insane on this point—in the construction of a great suit of subterranean chambers and galleries in his beautiful estate of Welbeck Abbey. The work included magnificently appointed stables for some hundreds of horses, and a vast riding school, the whole being illuminated by gas. Why he should have wanted to burrow underground when he had hundreds of broad acres on which to build, and a splendid old mansion above ground, no one but himself could tell. But there the excavations remain to this day, a monument of wasted time, labor, and treasure—of no earthly use or advantage.

A Steel and Glass Palace.

The latest thing in architectural oddities, however, is announced as being in course of construction in this country in the shape of a mansion constructed almost exclusively of steel and glass, which is to cost, not counting the decorations, the sum of $1,500,000. According to accounts given in the press a retired diamond mine owner from South Africa, said to be worth $25,000,000, has purchased a 500-acre tract in the Temescal district of California, where he purposes erecting for himself a lordly pleasure house which is not to contain a foot of timber or wood in any shape, and in which even the use of stone is to be restricted to a few marble and onyx sculptures and decorations. The material to be used will be iron, steel, aluminum, brass, bronze, copper, platinum, silver, glass, concrete and cement, the foundations being of steel and concrete. The building, as described in an architectural journal, will be about 230 feet long by about 100 feet wide. At one end it will be surmounted by a tower 115 feet high, at the other end by a similar tower, but of lesser size and hight. A striking feature will be the sides below the cornice, which slope to the ground with a curve at an angle of about 45°. In the sloping sides are set huge oval windows 12 feet long and made to conform to the line of the sides or walls. The roof will be a huge gable extending the entire length of the building and terminating in another gable at right angles, in which are placed immense stained glass windows, one of which will be 50 feet long and 30 feet wide. The roof is to be made of copper and the walls or sides of comparatively thin steel sheets. One would think this building would be intolerably hot in summer weather, while hail storms, which are not infrequent in that part of the country, would play havoc with the glass and cause a lively rattling on the metal roof and sides. On the whole, we should think a good old-fashioned frame house, costing but a small fraction of the sum mentioned for this mansion, would give a better return in solid comfort. Perhaps, however, the builder may be a crank on the subject of fires, in which case he might feel more at ease in such a thoroughly fireproof fabric.

THE LETTER BOX.

How to Line a Tank.

From J. J. B., *Philadelphia.*—I have read the letter of "B. H. T.," about lining a tank and your answer, and if he follows your method, I think, from his experience, taking his letter for my authority, you will give him more than he can handle. I have had considerable experience in that line as man and boss, and I will give him my method, and if he follows it he will have an easy thing. Get out his copper of sufficient hight to allow enough to turn over and nail on top and turn flange of 1½ inches on bottom. Form four corners square and turn edges same as for grooving; then get out copper for sides; edge and groove together, hooked in will answer (same as flat seam roofing), and don't be afraid of a hot iron or solder. For that size tank I would make copper ½ inch smaller than tank. He had better get out a strip and nail two right angle strips on ends, exact size of tank, for a gauge. Turn his 1½-inch edge on bottom. When he has it in tank turn ½-inch edge with tongs and put the bottom in, same as flat-seam roofing. He will have to notch top and bottom only one place so that sides and bottom will be brought together and allow it to slip in tank easily. If he follows that method and don't get it in his head that he has a big job, he is all right. Want of confidence is very often the cause of making easy work hard, and many failures. It is only one day's work for man and helper.

Cleaning Wipe Joints.

From SUBSCRIBER, *Santa Rosa, Cal.*—Will *The Metal Worker* please inform me of the best process for cleaning wipe joints after they have become soiled in stock?

Note.—If any of our readers have any better way than brightening them with fine sandpaper we will be glad to print their suggestions.

Area of a Circular or Elliptical Roof.

From D. L. W., *Madalin, N. Y.*—How is the area of a roof to be obtained that is either circular or elliptical in shape?

Answer—The area of a circle can be obtained by the use of any of the following rules:

Multiply the circumference by one-half the radius; or, by one-fourth the diameter.

Square the circumference (that is, multiply the circumference by itself), and divide by 12.56.

To obtain the circumference, use any of the following rules:

Multiply the diameter by 22 and divide by 7.

Or, multiply the diameter by 3.1416.

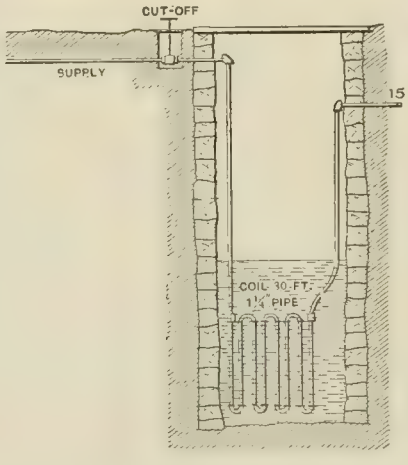
To obtain the area of a circle from the diameter, square the diameter and multiply by the decimal 0.7854.

To obtain the area of a circle from the radius, square the radius and multiply by 3.1416.

To obtain the area of an ellipse, multiply the product of the two diameters by the decimal 0.7854. Thus, supposing an elliptical roof to measure 5 x 8 feet, the operation would be performed as follows: $5 \times 8 = 40$, and $40 \times 0.7854 = 31.416$, or 31½ square feet in the roof.

Trouble With a Well Cooler.

From YOUNG MECHANIC, *Marshall, Texas.*—In answer to "P. R. F.," in *The Metal Worker* of July 1, he will find nothing better for cooling water for drinking purposes than a coil made of 1 inch or 1¼ inch iron pipe, using return bends and about 30 feet of pipe. I would also advise the pipe from the well to the sink to be put deeper under the ground, at least 3½ feet, to prevent the water being warmed by the ground before it gets to the sink. I have put in a number this way and never had a complaint. At one time the drinking slab was 200 feet from the well and had a creamery attached to it 15 feet from the well; ⅜ inch pipe was used from the coil to the faucet to lessen the amount of water drawn before the cold water came, as shown in Fig. 1. If he uses a boiler I would advise that it be connected like a range boiler with the boiler upside down, as in Fig. 2. The trouble came from the water passing straight through the boiler, and the cold water stands in the boiler as a dead end. I have never used a boiler for this purpose, but think he will find my suggestion will remove his trouble. I would advise the use of the coil with pipe cut short enough to be kept well under the water at all times. If he uses either of these suggestions, or some other, I hope he will give the readers his experience.



Trouble with a Well Cooler.—Fig. 1.—Plan Suggested by "Young Mechanic."

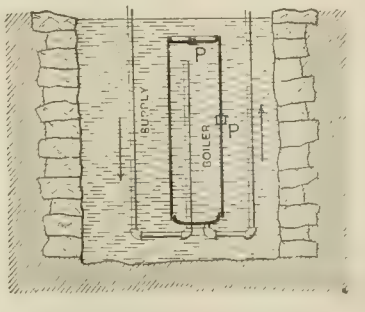


Fig. 2.—Vertical Boiler for Cooler.

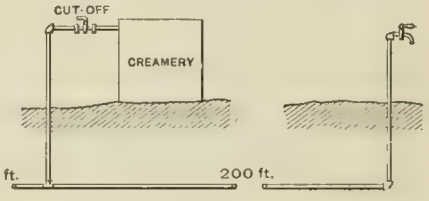
Note.—The operation of the cooler shown in Fig. 2 would be insured by the use of the opening in the top of the cooler for connecting a small pipe with a cock at the top end, conveniently located so that the air could pass out of the cooler as it filled.



Tapering Furnace Pipe.

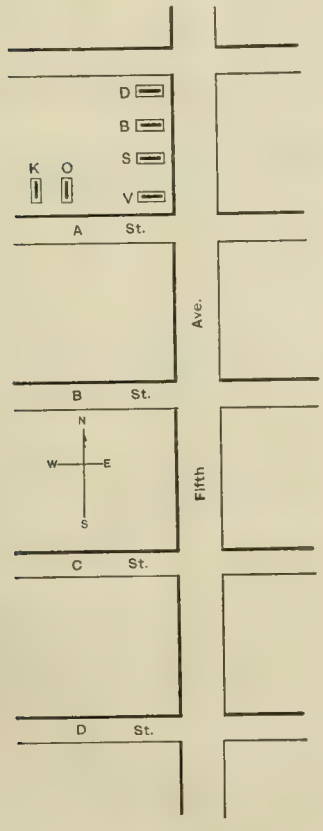
From J. F. T., *Meadville, Pa.*—There is a difference of opinion between A and B as to the best way of putting a hot-air pipe on a furnace. A contends that a pipe of any given length, say 12 feet, and tapering from a 12-inch collar to a 9-inch collar in the register box will discharge more hot-air than to reverse the pipe and start from the furnace jacket with a 9-inch collar and taper it to a 12-inch collar in the register box. We agreed to leave the question to you. Of course, B takes the opposite side of the question from A.

Note.—We doubt if the actual difference in the flow of hot air through furnace pipe arranged in the two ways mentioned would be noticeable, but there is probably some difference, nevertheless. Without having specific data on which to form an opinion we cannot do other than to mention some of the reasons why we think a pipe with the smaller collar at the furnace would carry the greater quantity of air. In either case, it is needless to point out, the air will have to pass through a 9-inch aperture. By having the 9-inch aperture 12 feet from the furnace the air will have an opportunity to cool in going that distance, and consequently the flow will be reduced in speed. On the other hand, if the 9-inch collar is at the furnace jacket the air passing through will be at the highest temperature, and as it cools in traveling the 12 feet of pipe there will be ample opportunity for it to escape, and consequently the speed of flow will not be materially reduced

and will not, therefore, put any back pressure on the air coming from the furnace. We would like to have this matter discussed by our readers, and if any of them can furnish results of practical experience their records will be the best basis for a settlement of the discussion.

A Chimney Problem.

From X. Y. & Z., *Washington.*—We have a problem before us which we would like *The Metal Worker* to help us solve. The sketch shows the location of the streets and D, B, S, V, O and K represent six cottages of seven rooms each besides the hall. A very steep grade runs up Fifth avenue, so that B, C and D streets are all higher



A Chimney Problem.

than the roofs of the cottages. The prevailing winds are from the southwest. The houses are all exactly alike in plan, each having a chimney in the middle of the house that has two openings in different rooms on both the first and second floors. The chimneys are 8½ inches square, clean and smoothly plastered inside and run clear down to the ground, but have no clean-out openings and have been built three and a half years. At all of the houses wood is used for fuel, generally pine, tamarack and fir. Houses D and O have "burned out" their chimneys three times each this year, and for the past four months have taken down their stove pipes every 30 days and cleaned them to avoid more fires. Each time considerable soot has accumulated, even in 30 days. At D and O what is called a Todd stove is being used, while at all of the other cottages direct draft wood-burning stoves are used. The pipes in these two houses show a hard, shiny deposit under the soot proper that looks as if moisture from some source had baked on. The soot cannot be scraped out clean, but only down to this deposit, which is not found in the pipes of the other houses. Only at D and O have fires occurred, though all of the other houses have run their stoves as strong. At O but one pipe has been connected with the chimney, while at D there have been two. All of the chimneys have a strong draft. What we want to learn is why do the chimneys at D and O burn out while the others do not, and what is the cause of their burning out three times since January 1, and what remedy can be applied?

Note.—The chimney, though an old institution, occasionally acts in a manner that baffles those who have had a wide experience in connection with it, and as a rule all remedies tend toward an improvement in the draft. It is generally conceded that an accumulation of soot is the result of a sluggish or obstructed draft. In the case in question the conditions are so nearly alike that the trouble is probably due to a purely local cause. There is seemingly no good reason why the two houses stated should be affected by outside conditions which do not affect the others. While a claim is made for a "strong" draft, the symptoms suggest a different state of affairs. The condensation noted would not occur in the pipe if a strong draft carried the vapors, arising from combustion, rapidly out of the top of the chimney, and the same is true regarding the soot that is now deposited. The Todd stove is sometimes made with a diving flue, which cools the products of combustion before they reach the chimney, so they have less buoyancy for rising than would be true of a direct draft stove. As there are other openings into the chimney they may be sufficiently open to partially supply the draft of the chimney, when the smoke would be left largely to dispose of itself, which it does in condensation and soot. Even though the chimney is supposed to be perfect throughout, a reduction in size where it passes some timber or a similar contraction may be found on search. An accumulation of broken bricks or other unexpected obstruction has often been found the cause of a deposit of soot.

Expansion of Metals.

From L. K., *South Norwalk, Conn.*—Kindly inform me through the columns of *The Metal Worker* the name of the metal which expands the quickest.

Answer.—The speed of expansion of metals is something we have never seen treated. It would depend upon the conductivity of the metal as well as upon its co-efficient of expansion. We assume, however, that our correspondent wishes to know what metal expands the most. At any rate, that is the question we shall answer, and if we are mistaken in interpreting his inquiry, we trust he will write us further. In the ordinary tables the greatest expansion is credited to zinc, which varies between $\frac{1}{329}$ and $\frac{1}{340}$ of its length between 32° and 212° F. The expansion for 1° F in a length of 100 feet for sheet zinc is 0.0196 inch; lead expands under the same conditions 0.019 inch; tin expands 0.0145 inch; copper 0.0115 inch.

Trouble with Water Back.

From H. W. Hess, *Portland, Maine.*—In *The Metal Worker* of July 15 is a letter from "J. P. & S.," Haddonfield, N. J., in reference to trouble with water back. I have many times in 30 years' experience found just such trouble, and, as a rule, I have discovered the cause in the water back. A short time ago I met with the same difficulty. By running the fire for all it was worth I could not get the water hot enough to wash dishes, but by taking out the back and putting in its place a brass coil it gave entire satisfaction. As I was curious to know what the trouble was, I broke the water back in pieces and found that the iron was so thick on the side next to the fire that it could not become hot. I think if "J. P. & S." will try the brass coil they will have no trouble in heating water.

Removing Zinc from Tin.

From A. M. C., *Leonardsville, N. Y.*—Will you kindly give, through the columns of *The Metal Worker*, some way for removing zinc from pig tin which has been used in tinning iron. The quantity of zinc is small, but enough to prevent working?

Answer.—In *The Metal Worker* recently the following method was given for cleaning solder that contained zinc, which possibly will answer for cleaning tin: Burn sulphur on the surface of the melted metal, stirring it constantly to bring the zinc in contact with the burning sulphur and remove the dross with a skimmer. "C. W. B.," Fresno, Cal., seeing that method, stated later in the Letter Box that he used common salt with as good or better results, and found it much less disagreeable to use. We shall be glad to hear from those who have had experience in cleaning tin if better methods exist.

Stove Makers Criticised.

From S. & W., *Walden, N. Y.*—We are not doing so much in stoves now, but will soon have to be buying, and would like to know from other readers of *The Metal Worker* what they think of the way stoves are put together. If the stove manufacturers would take the dealers into their counsel a little when they are getting up stoves so many bolts and nuts would not be put in such out of the way places where they cannot be got at. When repairs are necessary and the nuts rusted fast great danger of breaking is run if an attempt is made to cut them, or much time and hard labor must be spent if a breast drill has to be used.

Note.—The theme of our correspondent is not new, yet it is interesting, and if discussed may bring some new fad, making the rods, bolts and nuts used in stove construction an ornamental feature.

Air Supply Filter.

From W. M., *Ohio.*—It would be interesting to me, and probably others, if the readers of *The Metal Worker* would give in The Letter Box what they have used for screening air entering the cold-air boxes of hot-air furnaces in sections where soft or bituminous coal is largely employed for fuel.

Note.—This is a question that is growing in interest and we hope our readers will respond to the inquiry and describe in detail the plans and apparatus they adopt.

STEAM AND HOT WATER.

The Marsh Improved Air Valves.

James P. Marsh & Co., 224–226 Washington street, Chicago, are putting the improved air valves herewith illustrated upon the market. The No. 2, shown in Fig. 1, is mentioned as having a large and strong drain-pipe connection, absolutely tight. The No. 3 A, Fig. 2, is said to fulfill all the requirements that can be demanded by the most exacting fitter. It is provided

The Marsh Improved Air Valves.—Fig. 1. —The No. 2 Valve.

with a large evaporating cut or air moistener, which is claimed to be very effective. The No. 3 A valve has been applied in the following Chicago buildings: Marshall Field Building, Art Institute, Isabella Building, Chicago Beach Hotel and Windermere Hotel.

Fig. 2.—The No. 3 A Valve.

The following statement is taken from a catalogue recently issued by the firm:

Automatic air valves are absolutely necessary if a steam coil or radiator is to be continuously active in radiating heat. As air and steam cannot occupy the same space at the same time the air must be allowed to escape, in order that the radiator may be hot. This must be done automatically, for the ordinary air cock does not get the requisite attention.

The Marsh patent automatic air valve is constructed on purely scientific principles. The composition of the expansion tube is such that it will always contract to its original length when cooled, and makes the valve, therefore, perfect in its action without the variation shown in others even when properly adjusted. The waved sides give an elasticity to the U-shaped rust-proof steel rods which hold the stationary part of the valve, and prevent accidental injury to the seat of the valve, or the striping of its thread, so common in other valves when they have been screwed too tightly.

HEATING NOTES.

E. D. Smith of the firm of Baker, Smith & Co., New York City, has been elected a member of the Executive Committee of the Master Steam and Hot Water Fitters' Association of the United States to fill the vacancy caused by the resignation of George H. Morris, who found it inconvenient to serve.

Contracts for steam heating and ventilating apparatus for the Government, at Plattsburg, N. Y., will soon be awarded.

Petition has been made to the court far a better system of heating and ventilation in the Court House, at Lock Haven, Pa.

Bowker & Tripp, New Bedford, Mass., have taken the contract for installing a steam-heating plant for the New Bedford Button Company.

Some of the contracts now being filled by T. B. Coyer & Co., Newark, N. J., are the installing of a No. 58 American safety sectional boiler for steam, made by the American Boiler Company, with 1300 feet of the American Radiator Company's Perfection radiators, at 128 Chambers street, New York, for Samuel Colgate; a No. 26 Perfect hot-water boiler, with 900 feet of Detroit radiation, in the residence of Harry Hunneke on 170th street, and a No. 3 Surray hot water boiler, made by the J. L. Mott Iron Works, with Detroit radiation, in the residence of E. J. Bimbler, at Newark, N. J. They have just completed the erection of a steam-heating plant in the St. Barnabas Hospital, at Newark.

The contract has been awarded to the Falls City Heating & Plumbing Company for installing the heating apparatus in the new City Hall, at Spokane, Wash.

A patent has been granted to Nelson Curtis, Boston, Mass., for an improvement in pressure regulators, the invention relating to that class of regulators by which the pressure of the fluid-operating mechanism of the system to which the regulator is applied is controlled by the pressure of a separate fluid. The invention consists of a detail of construction, the principal feature of which is a hook, by the use of which the usual directions of the two forces controlling the auxiliary valve are reversed.

Contracts not to exceed $1200 will be made to secure sanitary appliances and steam heat for the Russell School, at Pittsfield, Mass., if the School Board can get the appropriation from the City Council.

The J. F. Pease Furnace Company, Syracuse, N. Y., have been awarded the contract for heating the Academy building at Windsor, N. Y. A combination system of steam and hot air will be used.
